

Grizzly-PAW: Grizzly Population
Assessment in yellowhead: Integrated
Approaches Toward Conserving Grizzly
Bears On A Human-Dominated Landscape
Of Western Alberta.

Show Case of Research Outcomes

Nicholas Coops
October 18th 2019

Thank You for Attending

- Many thanks to all attendees for travelling long distances and taking time from their busy schedules
- Special thanks to industrial sponsors for attending, both this morning and this afternoon
- FRI Research
- TransCanada for hosting us in Calgary
- University faculty, graduate students and postdocs – some of whom now have jobs and taken time off to attend

Context for the Proposal

Conservation of Grizzly Bears in Western Alberta

- Grizzly bears are considered a threatened species in Alberta from 2010
- From a management perspective there is uncertainty about current population levels and how anthropogenic landscape change and human activities have affected grizzly bears in Alberta in the past and into the future.

Industry Needs

8 key questions asked by Industry which this proposal aims to address

- NSERC Collaborative and Development Project (CRD)
 - 4 year project (3 years of funding)
 - Approved for funding in July 2016
 - End in June 2020
- As most projects are coming to an end an opportunity to see research outcomes and share internally within the project and with wider community

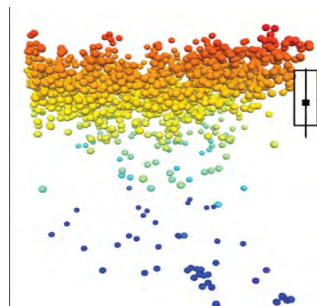

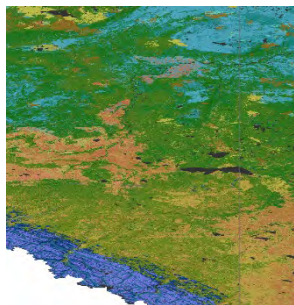

Three thematic areas of research and scales:

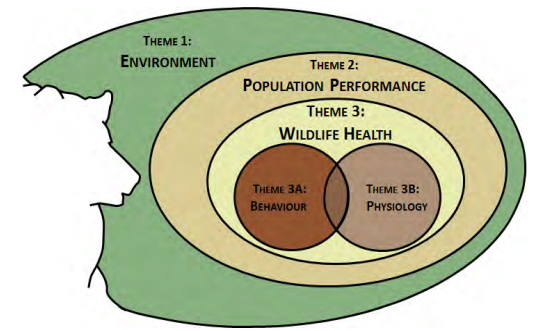

- (1) the environment that sets the broader landscape and environmental context of the Yellowhead bear management unit;
- (2) demographic responses relating to population status, size and change; and
- (3) wildlife health which involves individual-animal responses relating to their (a) behaviour and (b) physiology

Today

- *In the Afternoon:*
- Open to other interested researchers / industries
- Summary talks by the lead faculty members
- Posters on each project for further discussion
- Chance to discuss future research opportunities / ideas

What is the Current Environment in the Yellowhead and how is it changing for Grizzly Bears ?

Can we describe patterns of forest harvesting, oil and gas exploration, mining as well as urban development ?

1984

NBR index

ECO-ANTHROMES

A wall-to-wall, disturbance-informed ecological regionalization (30 m) for Alberta, Canada for the period 2006 – 2015

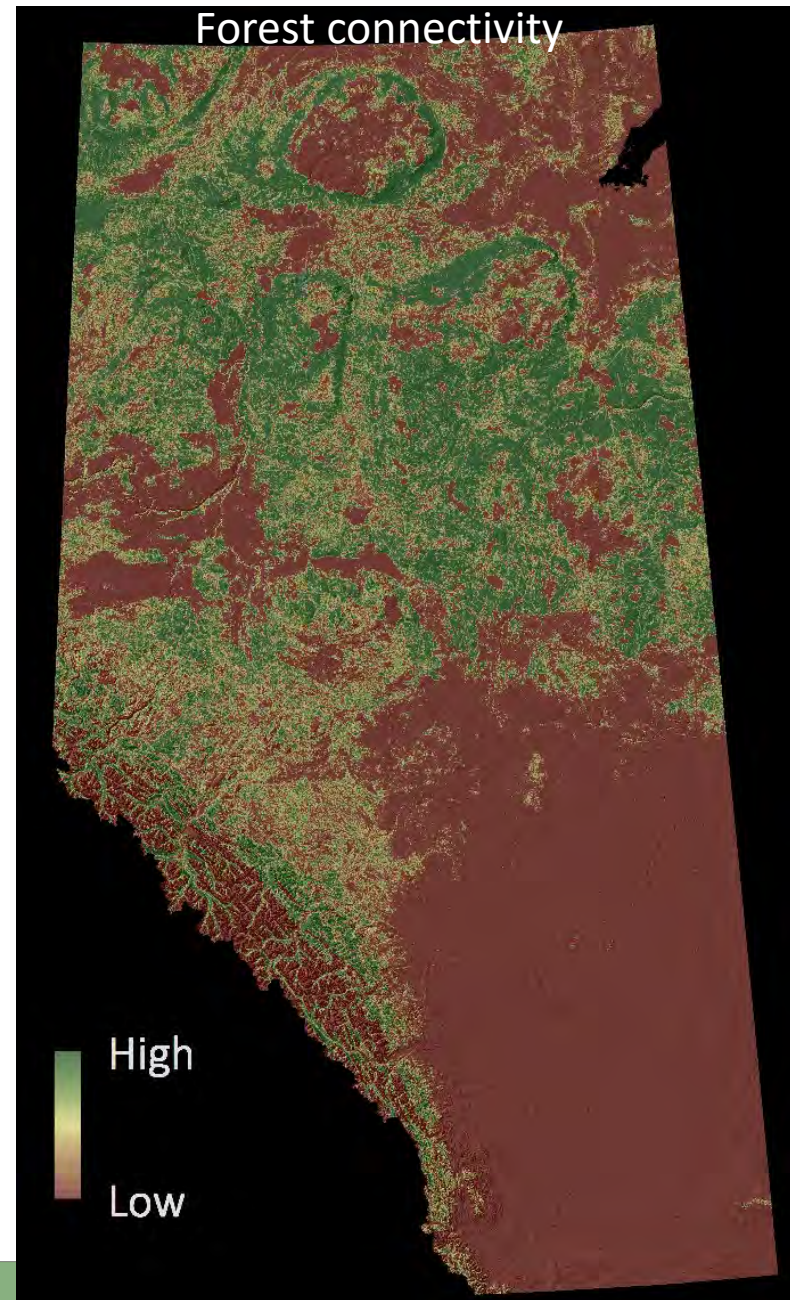

Two-step clustering
algorithm

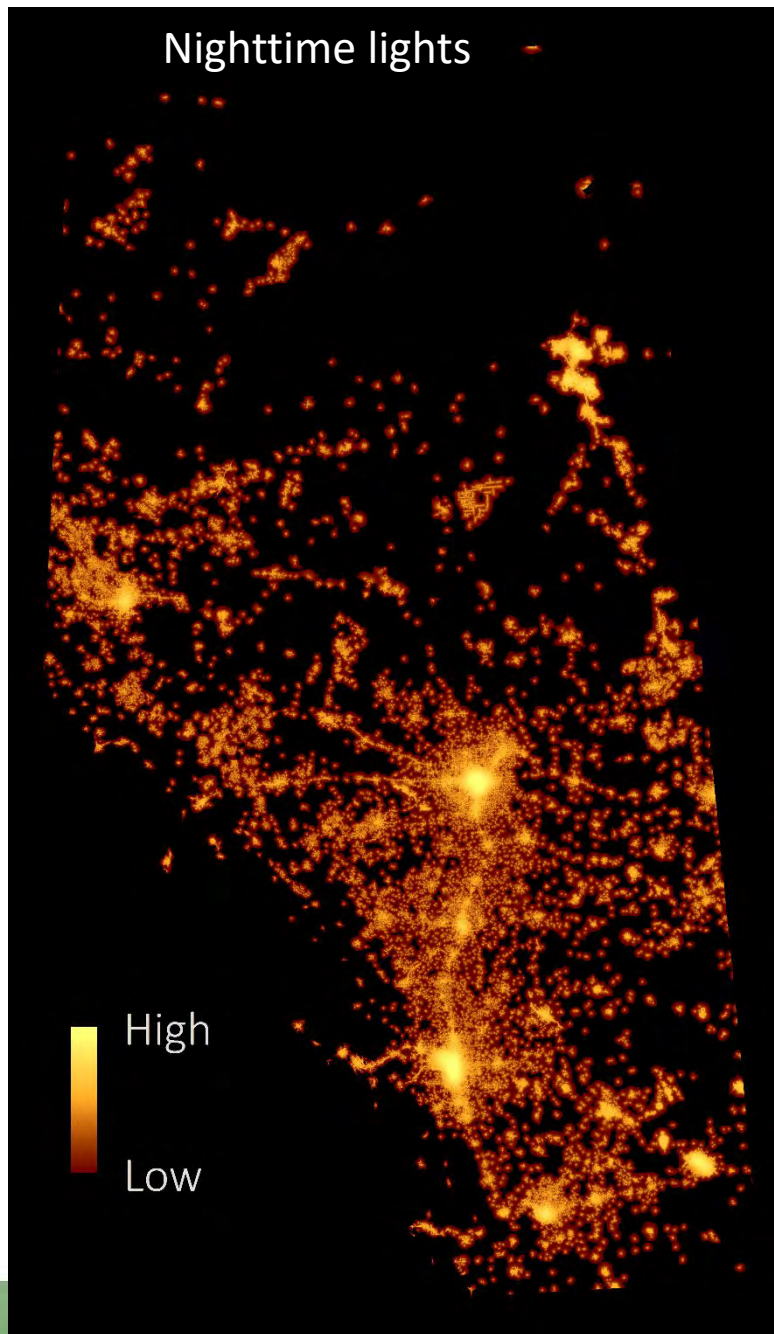

Surface greenness

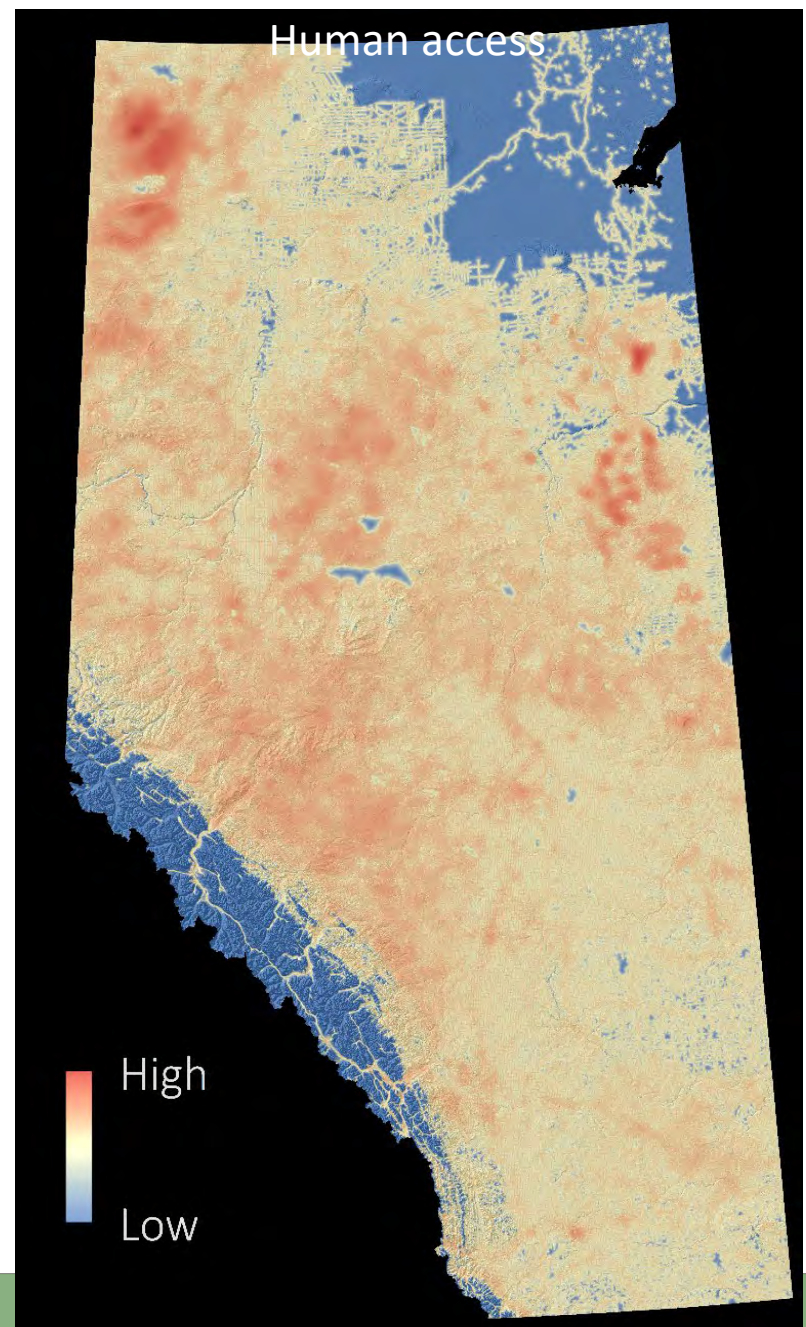

Forest connectivity

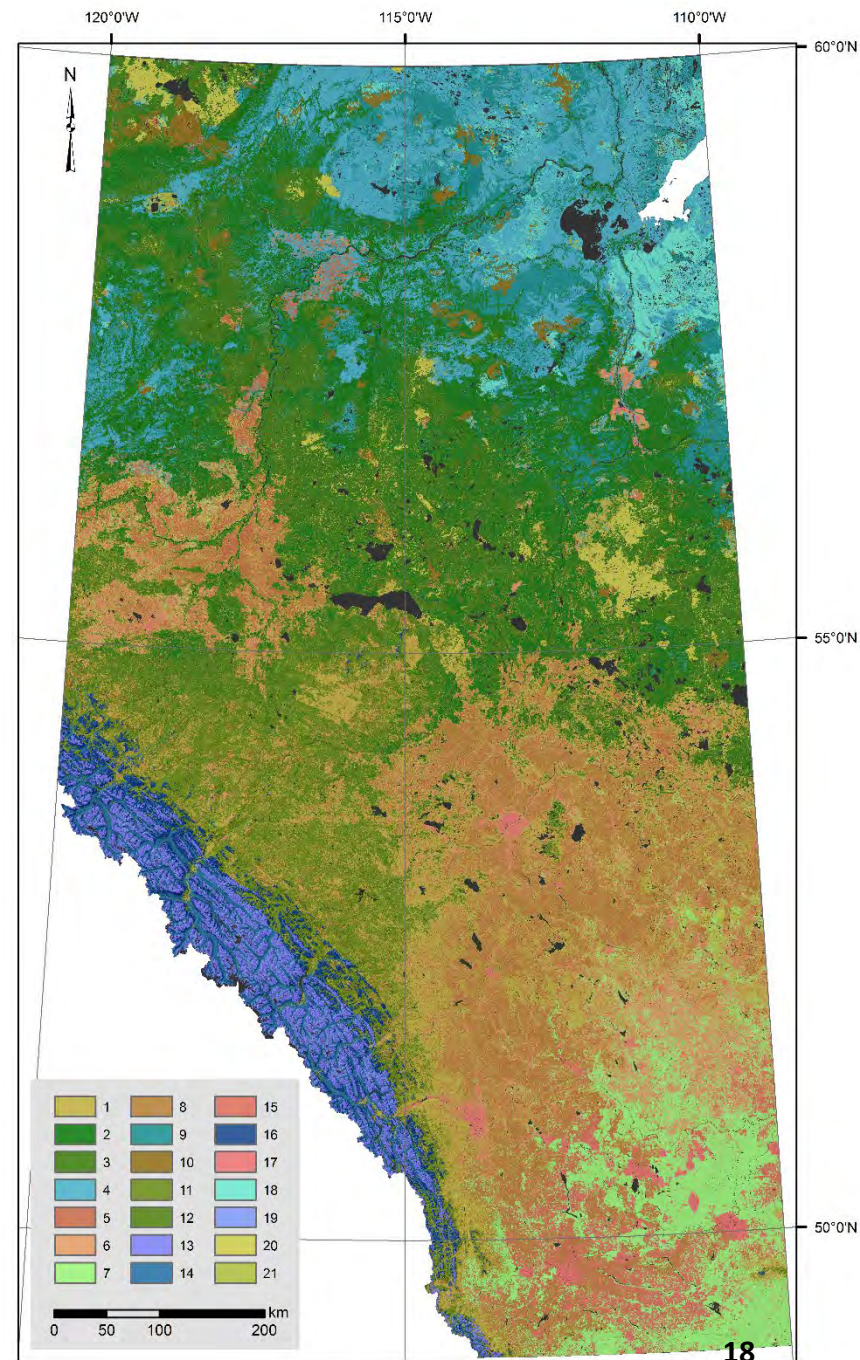

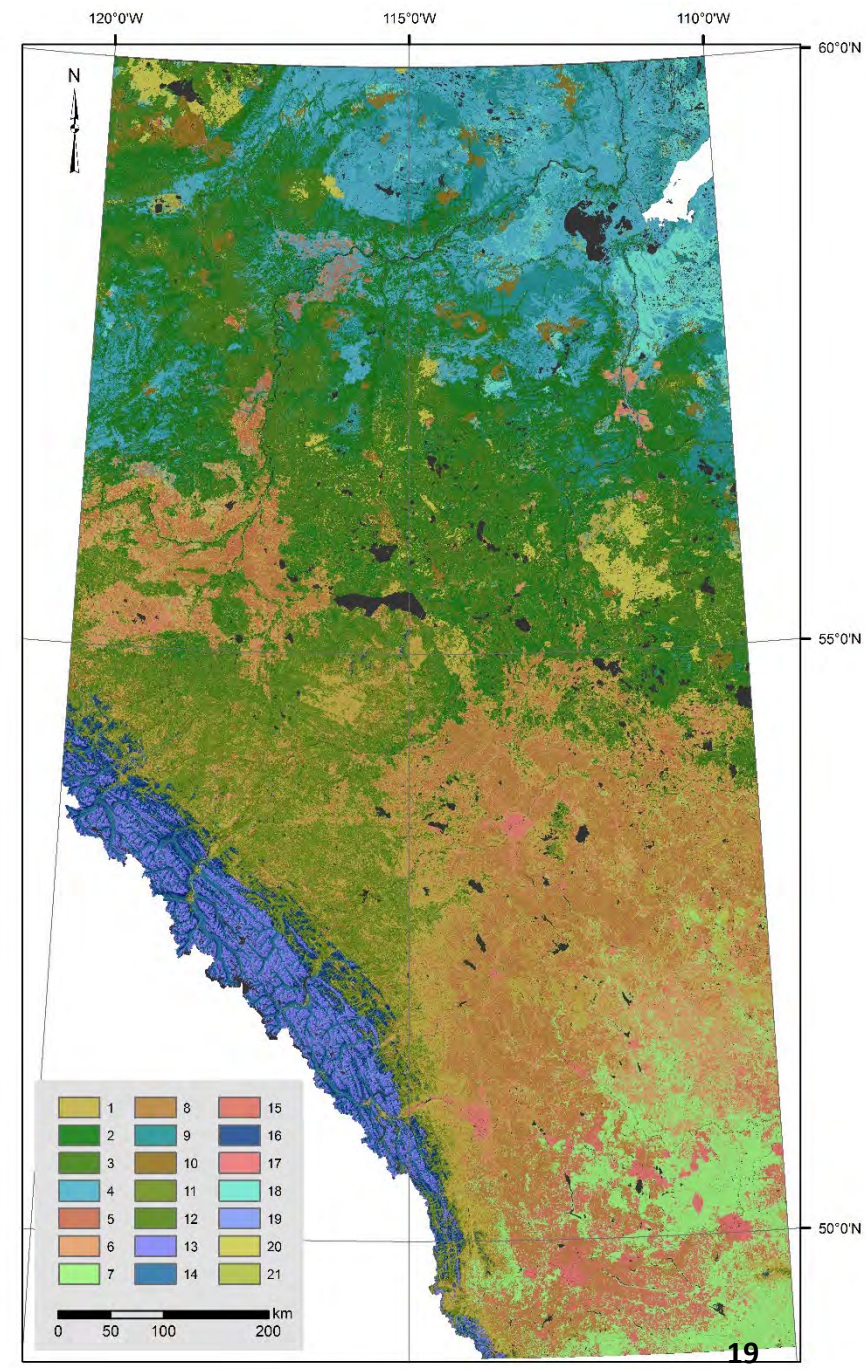

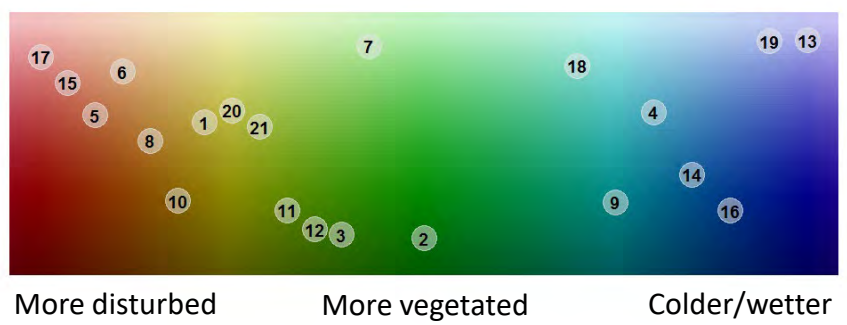

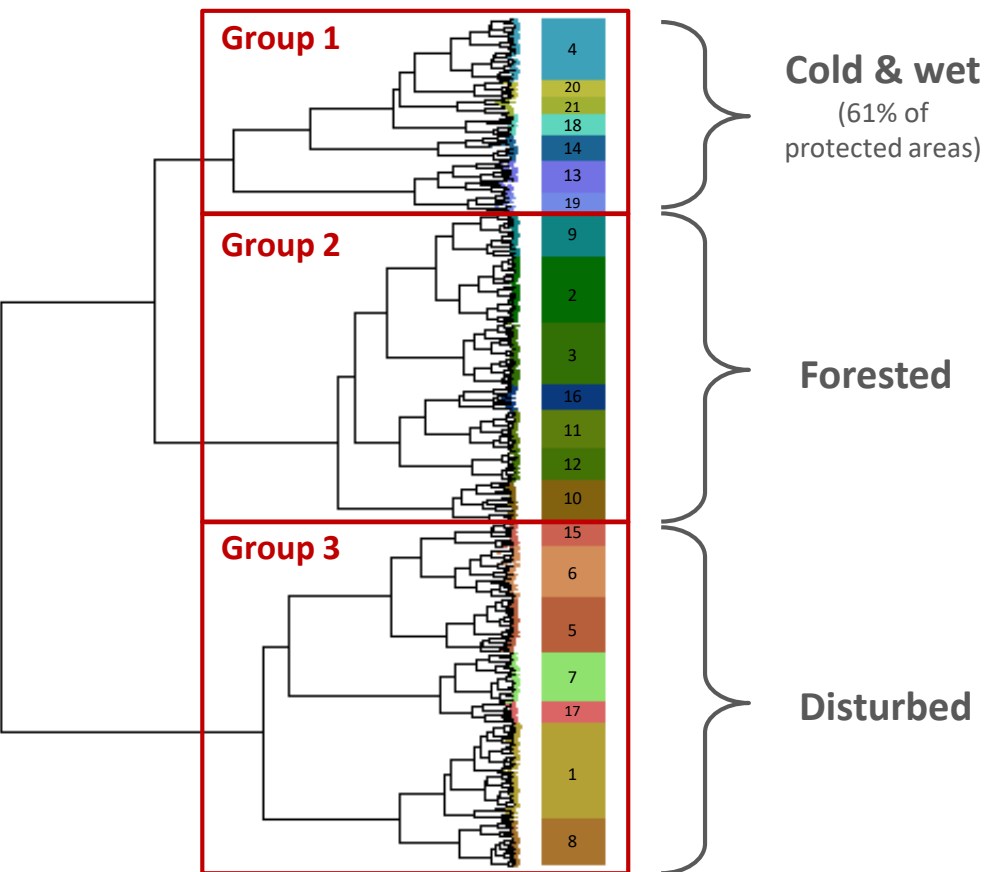

Nighttime lights

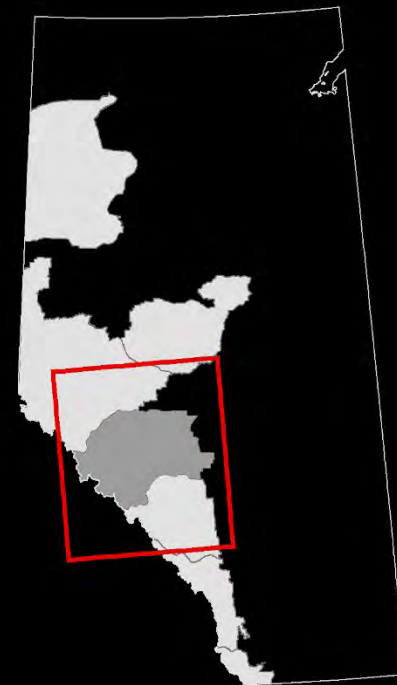

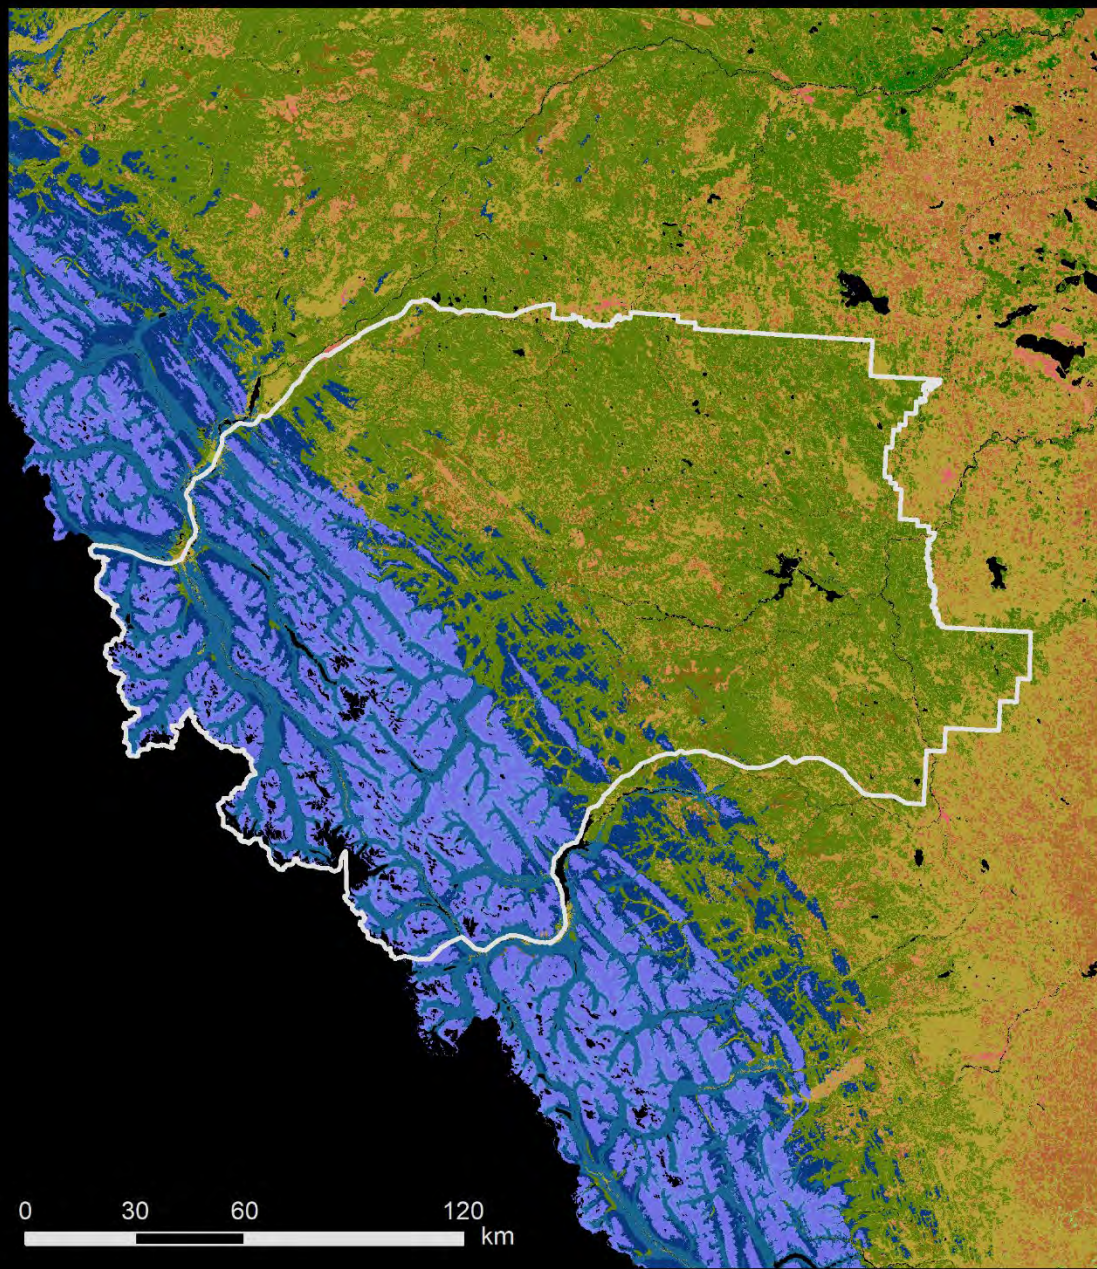

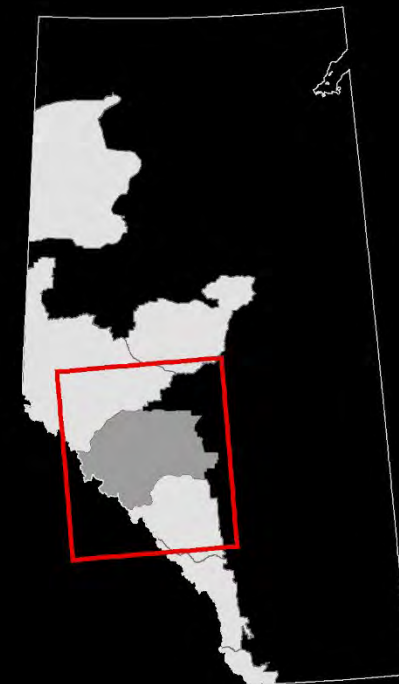

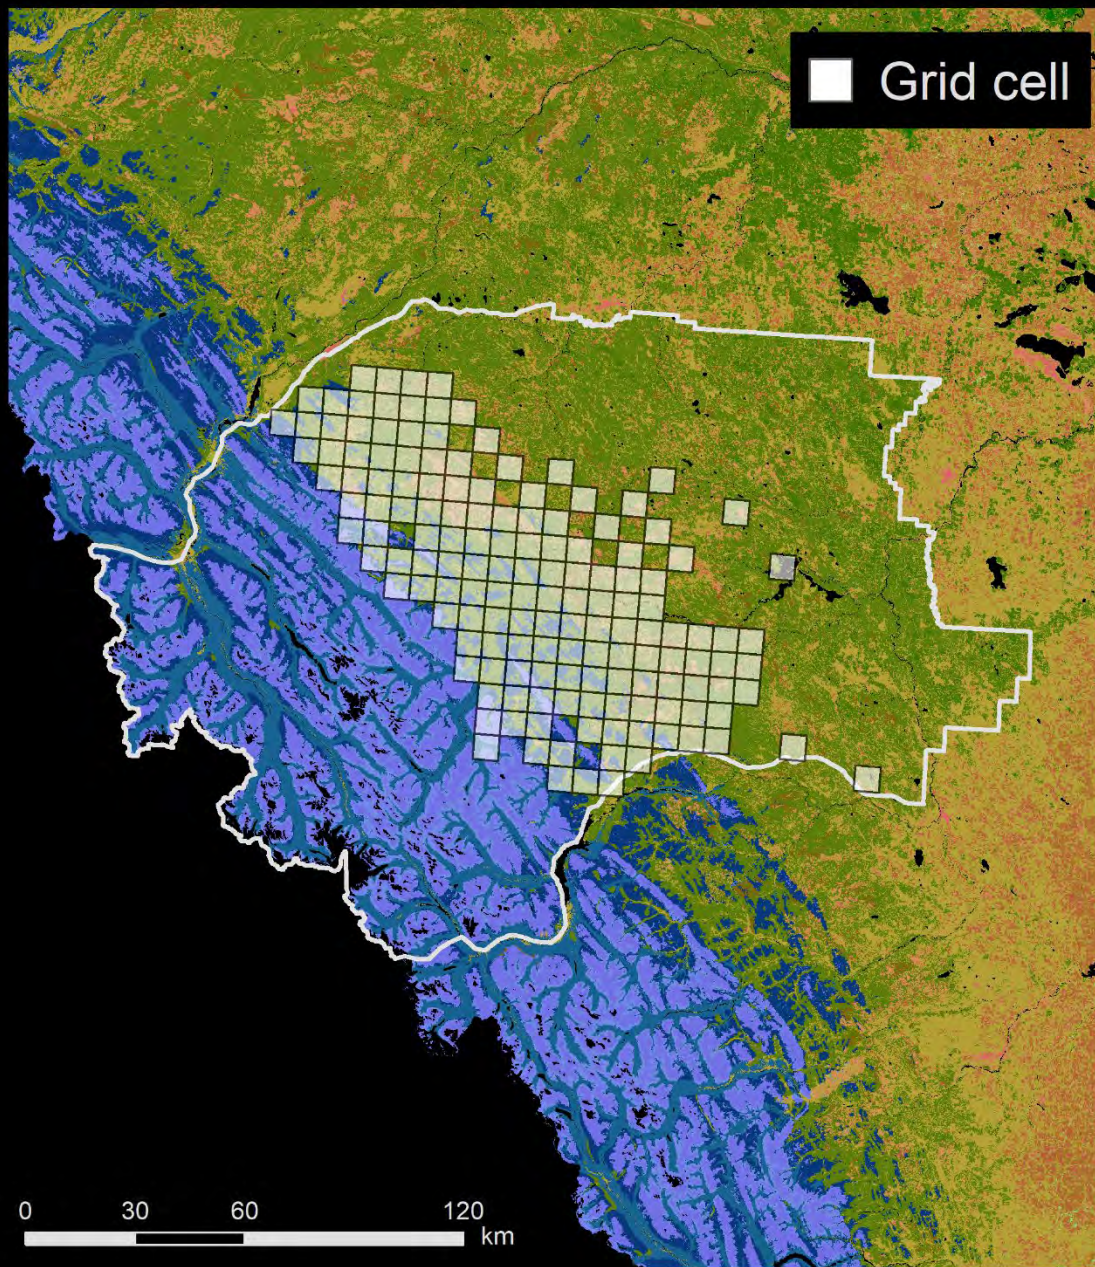

Human access

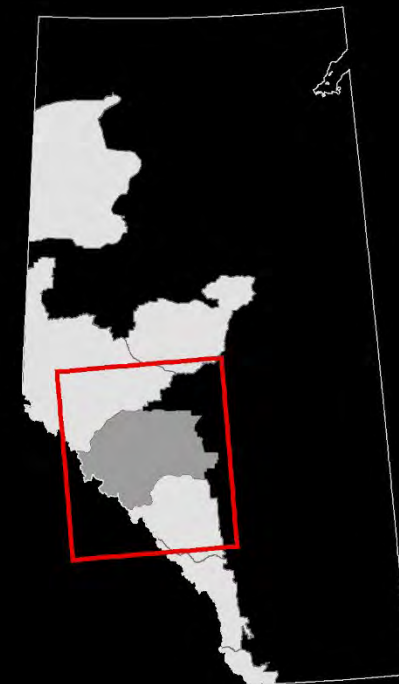

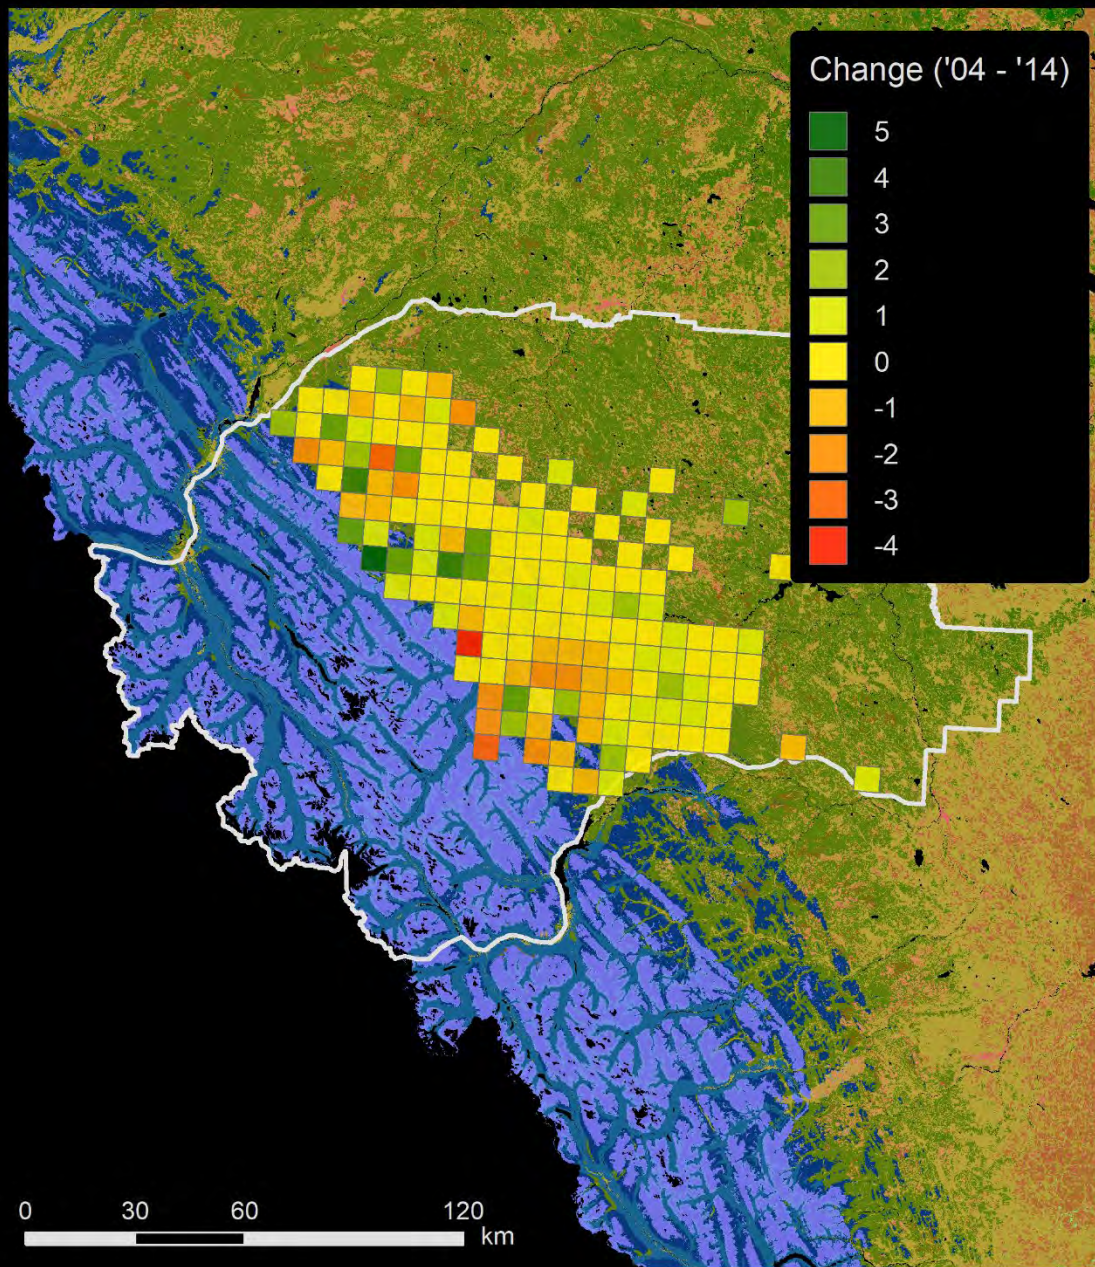

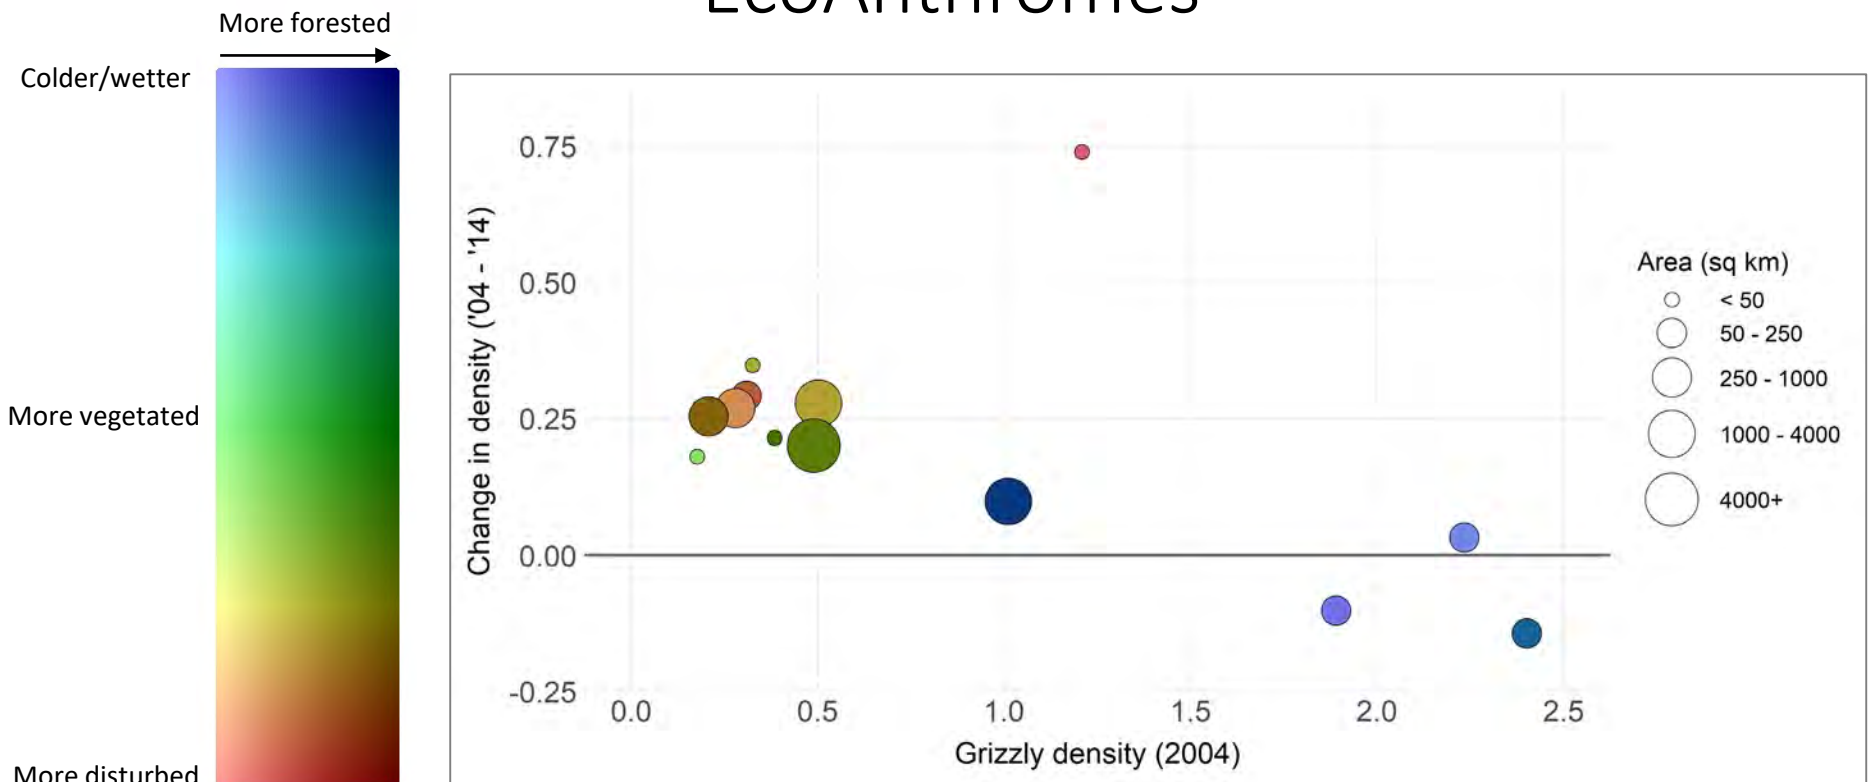

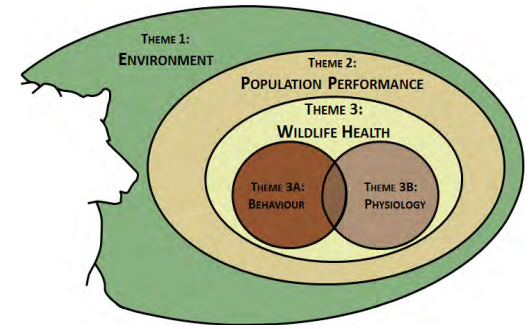

Change in grizzly density by EcoAnthromes

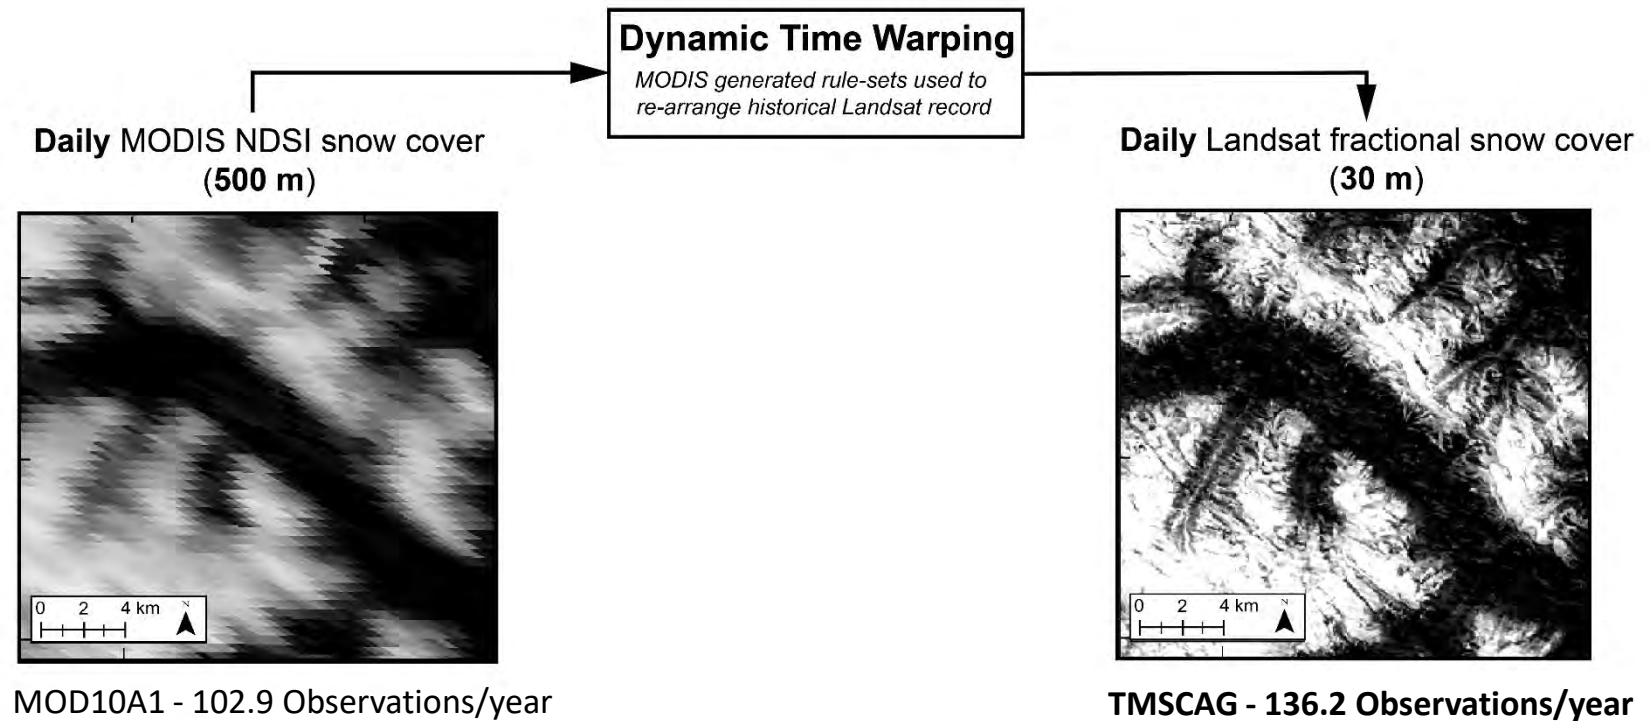

- Density increased more in **disturbed** regions
- Density is higher but declining in **colder/wetter** regions
- Grizzlies may be moving into lower elevation, human-disturbed areas from high-density regions

What about the Snow Cover and how it is changing ?

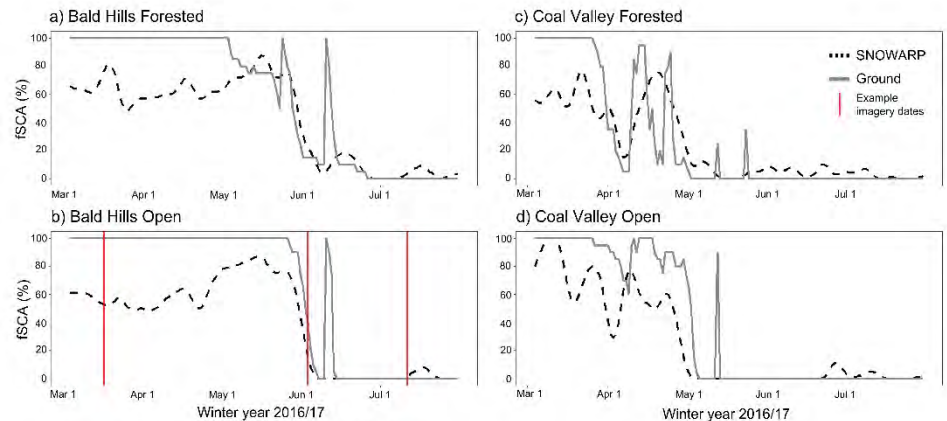

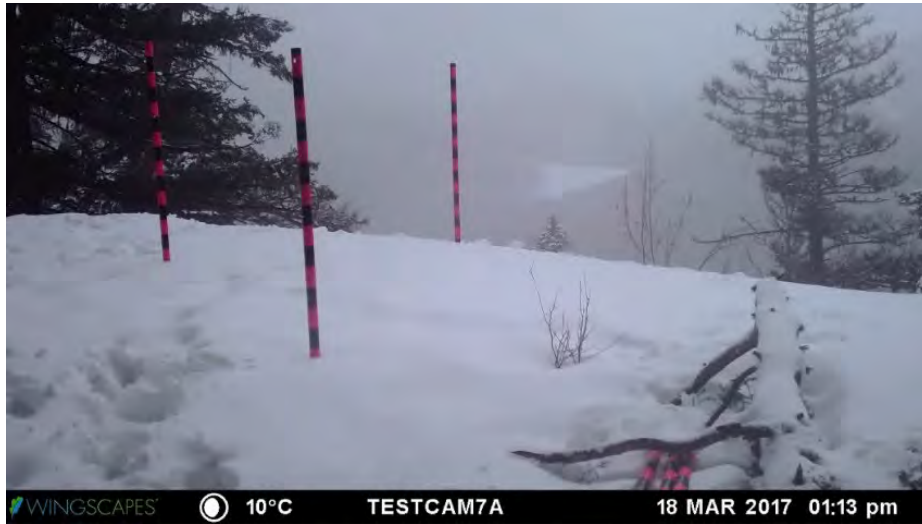

Are we seeing changes in snow accumulation and melt and is it impacting bear behaviour ?

SNOWARP: Daily 30-m Fractional Snow Covered Area (fSCA)

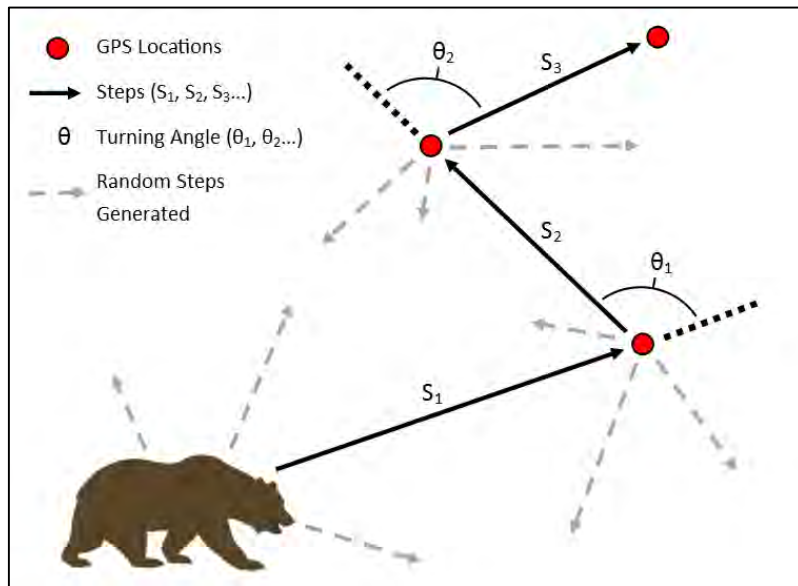

Ground-Based Testing

e) Example time-lapse imagery from Bald Hills Open

Modelling Approach

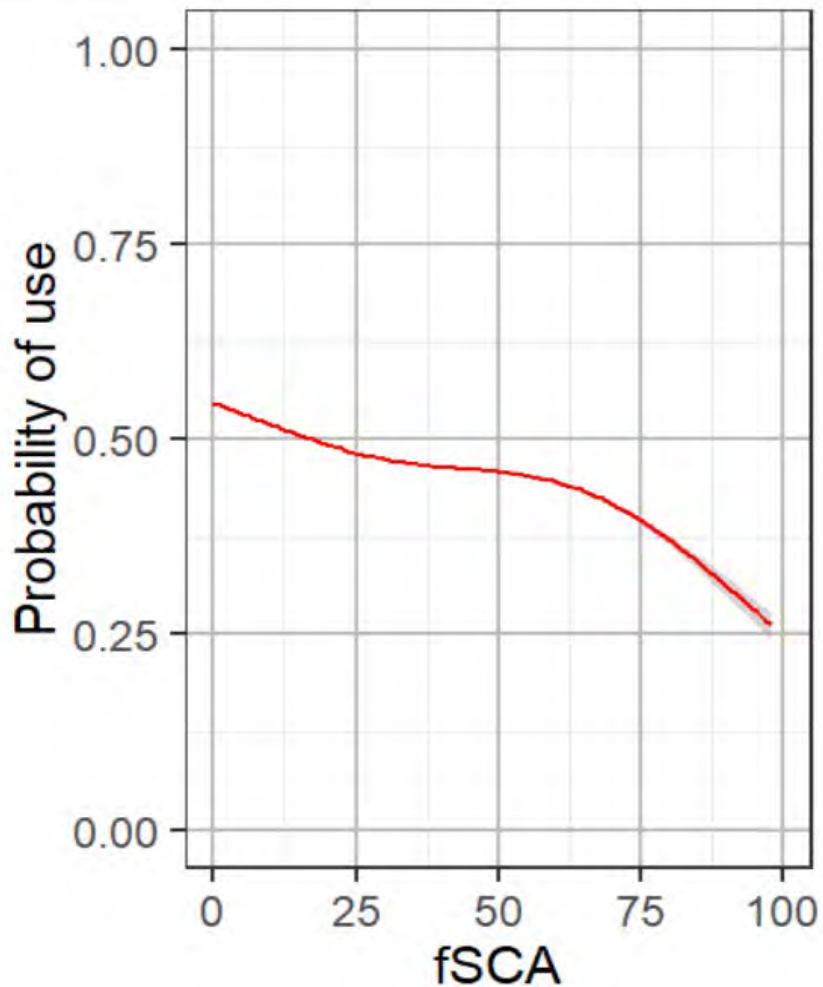

- Used vs. Available steps
- Core Environmental Variables
 - Step length, time of day, elevation, distance to road, terrain wetness, distance to forest edge, landcover, solar insulation
- Snow Variables
 - Fractional snow covered area, binary snow covered area, days since snow melt

Model Comparison

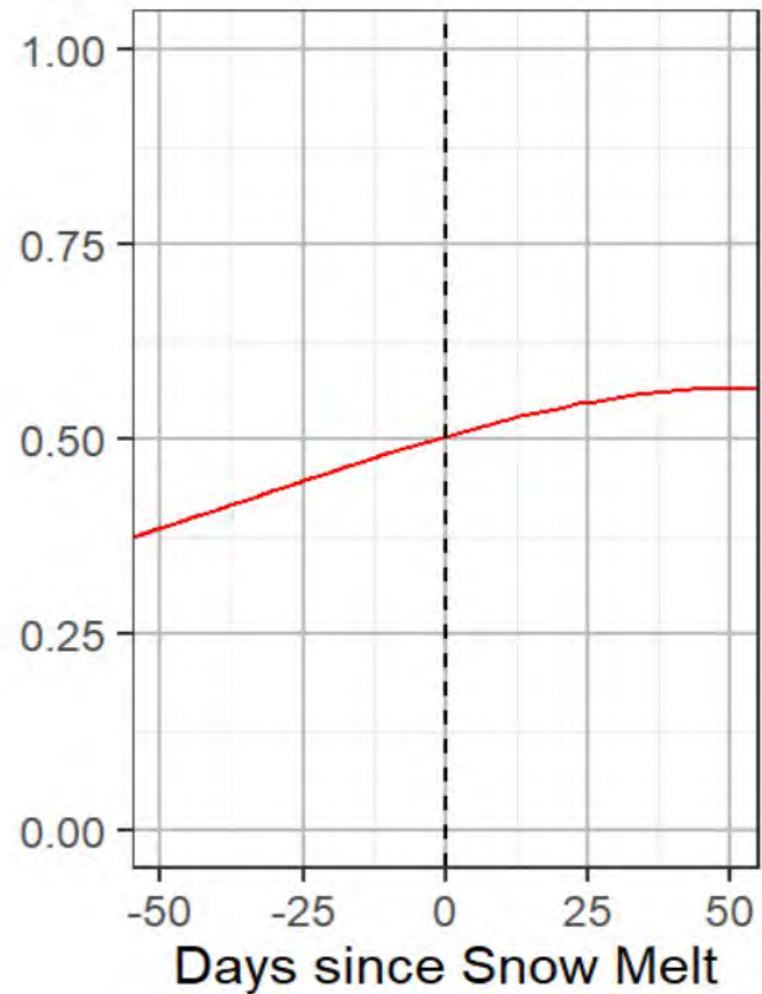

Model	AIC Tally	Average AIC Weight
Core	11	0.1460
Days since snow melt (DSM)	9	0.1508
Binary snow covered area (bSCA)	5	0.1357
Fractional snow covered area (fSCA)	37	0.5675

How does snow influence grizzly bear use of the landscape?

a)

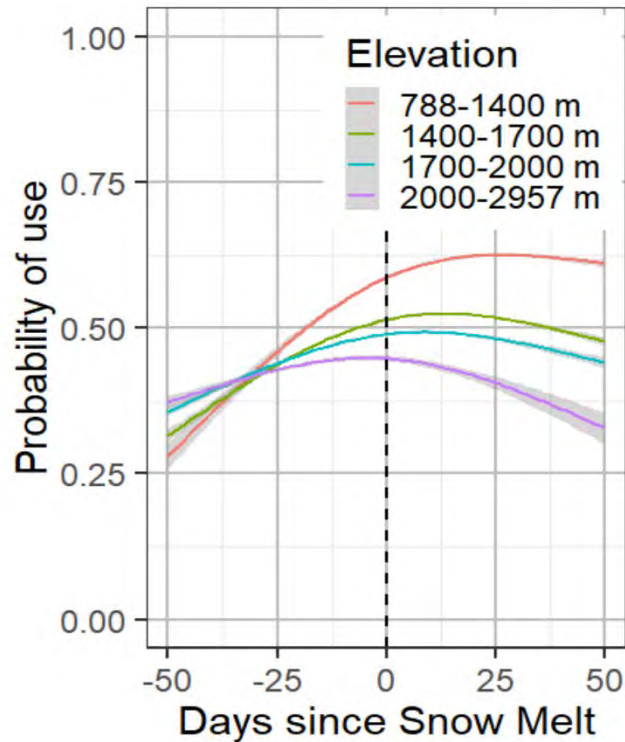

b)

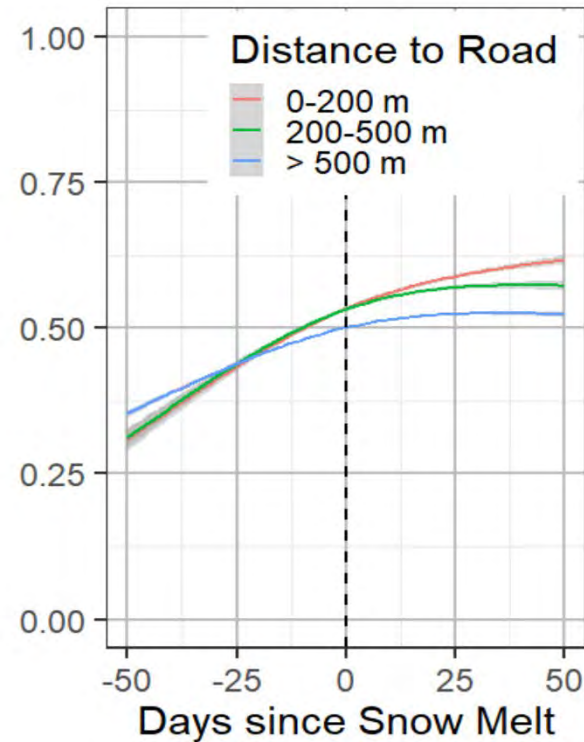

More likely to use snow free areas and areas where snow melted sooner

a)

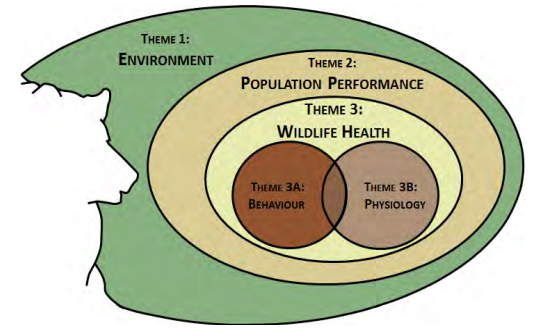

More likely to use lower elevation locations, especially when snow free/earlier melt

b)

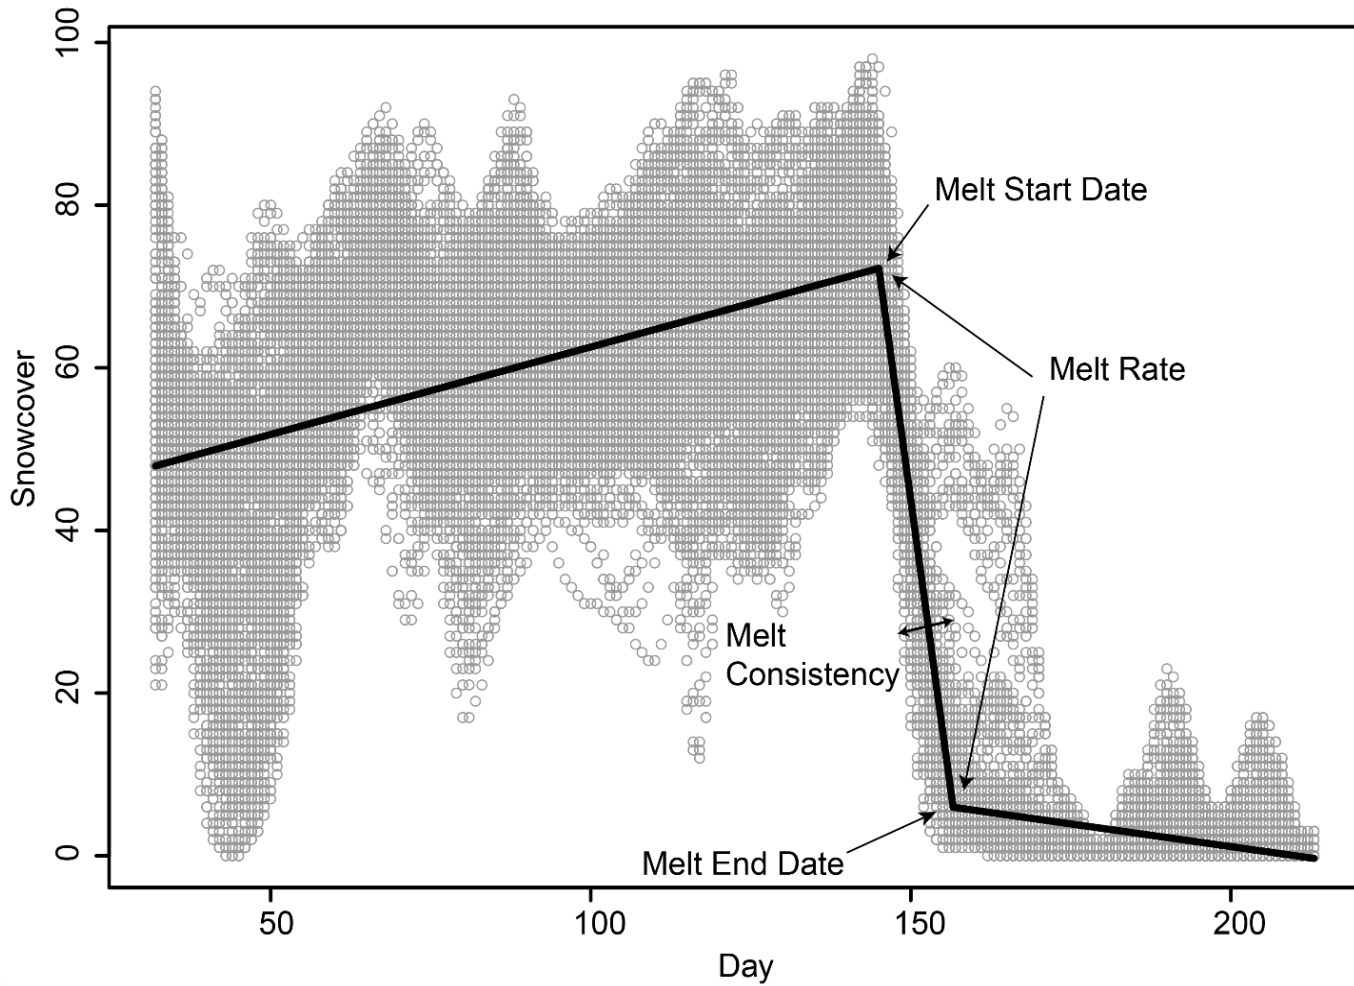

More likely to use locations closer to roads, especially after snow melt

What about the Snow Cover and how it is changing ?

Are we seeing changes in den emergence with changing snow conditions?

Methods

Results

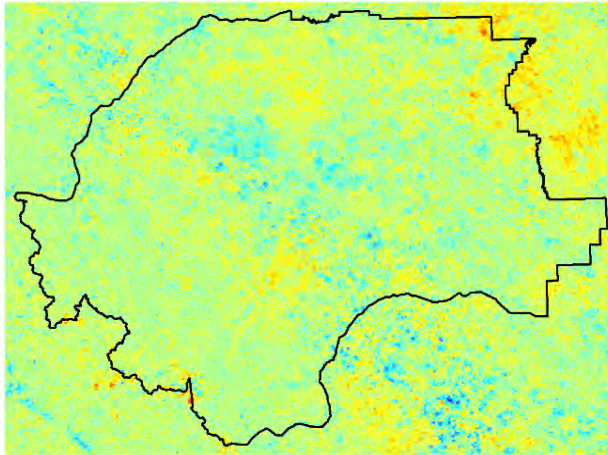

Individual bear activity date highly associated with three snowpack variables

- Earlier melt end date = earlier activity date
- More rapid melt rate = earlier activity date
- Less consistent melt = earlier activity date

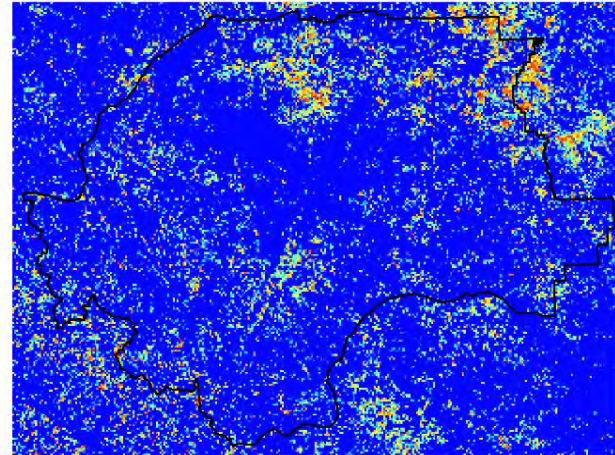

These three variables explained 45% of variation in individual activity date

Results

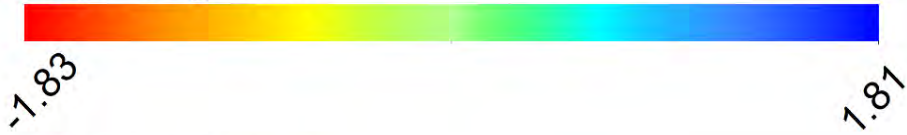

Theil-Sen's Slopes

Mann-Kendall p-Values

Slope Magnitude

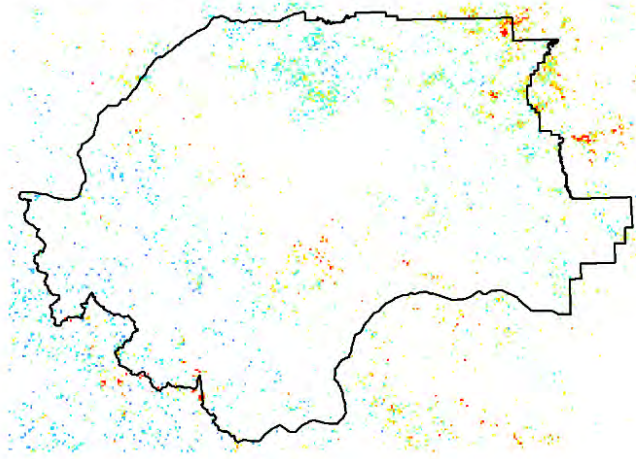

p-Value of Slope

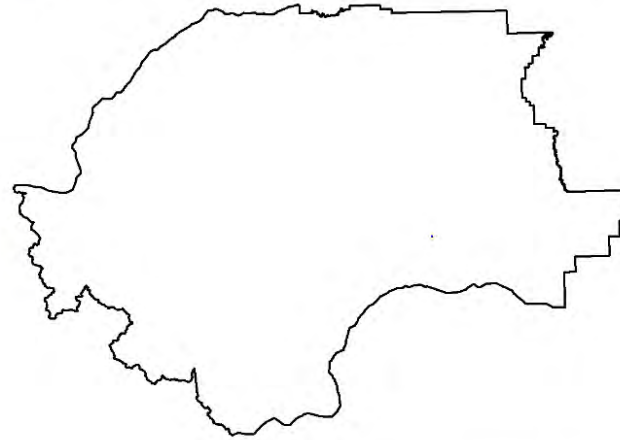

Results

Significant Negative Slopes

Significant Positive Slopes

Bear Activity Date Change

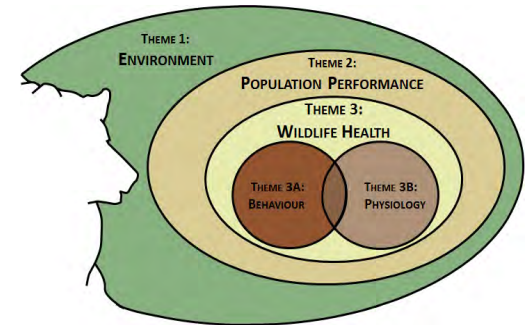

Greater

Lesser

What about the food availability and how it is changing ?

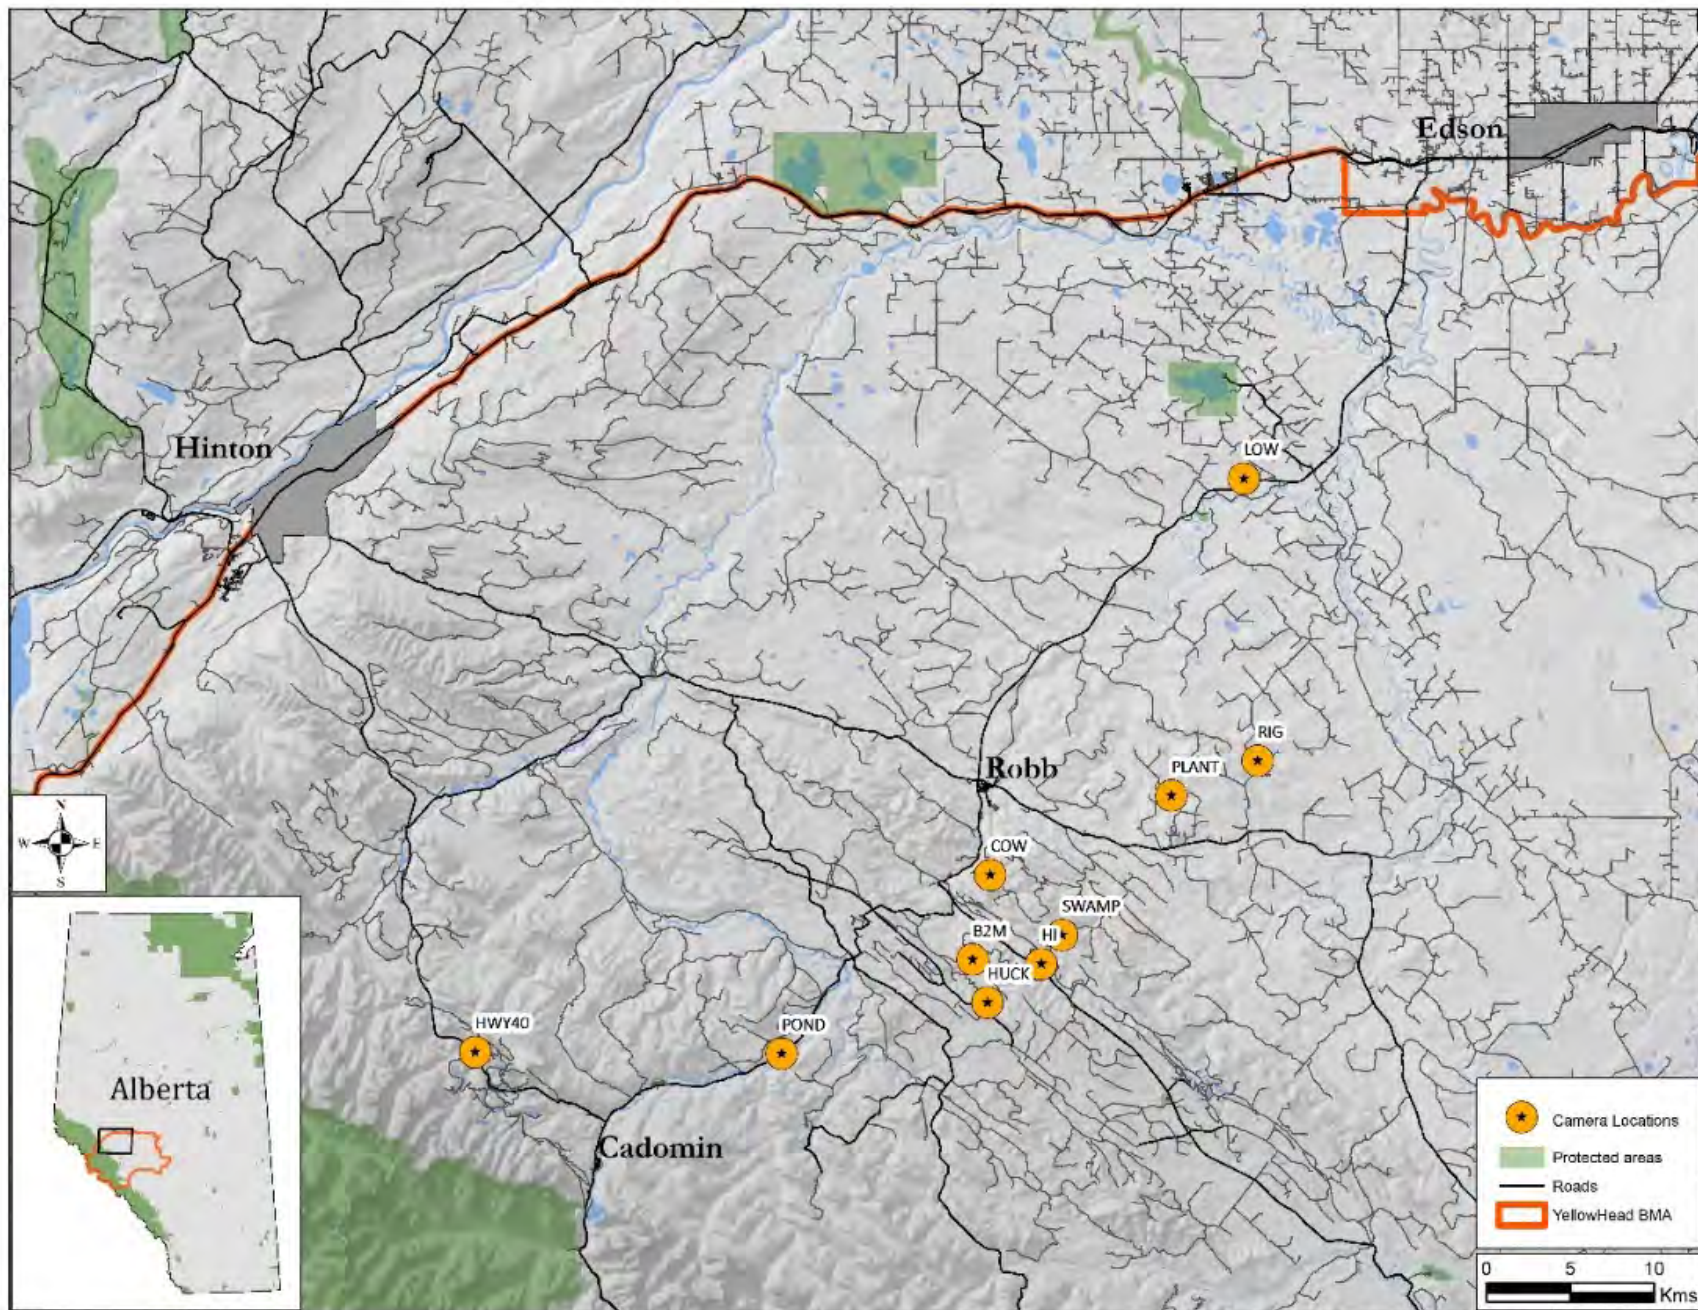

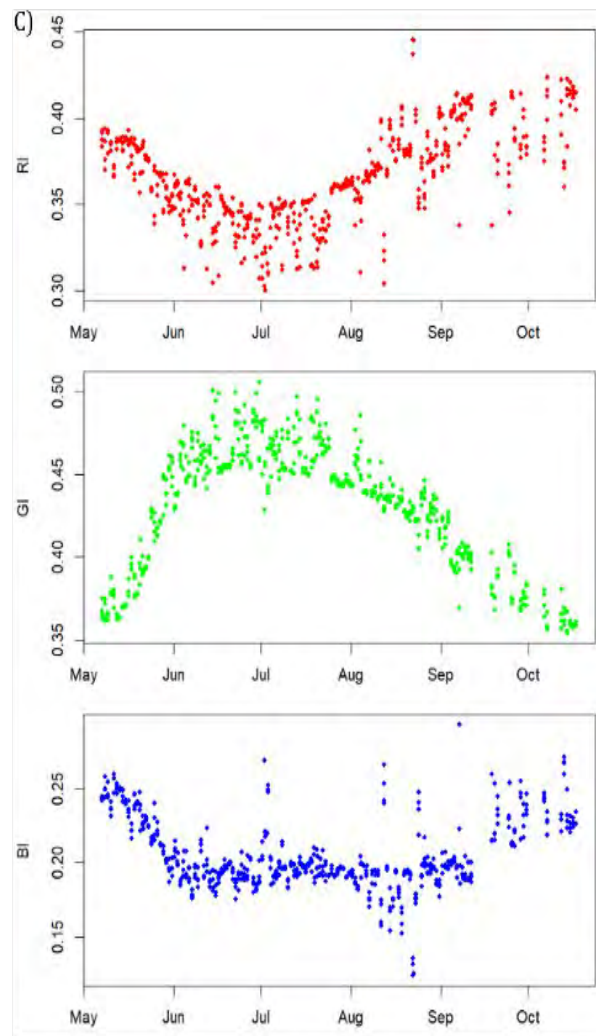

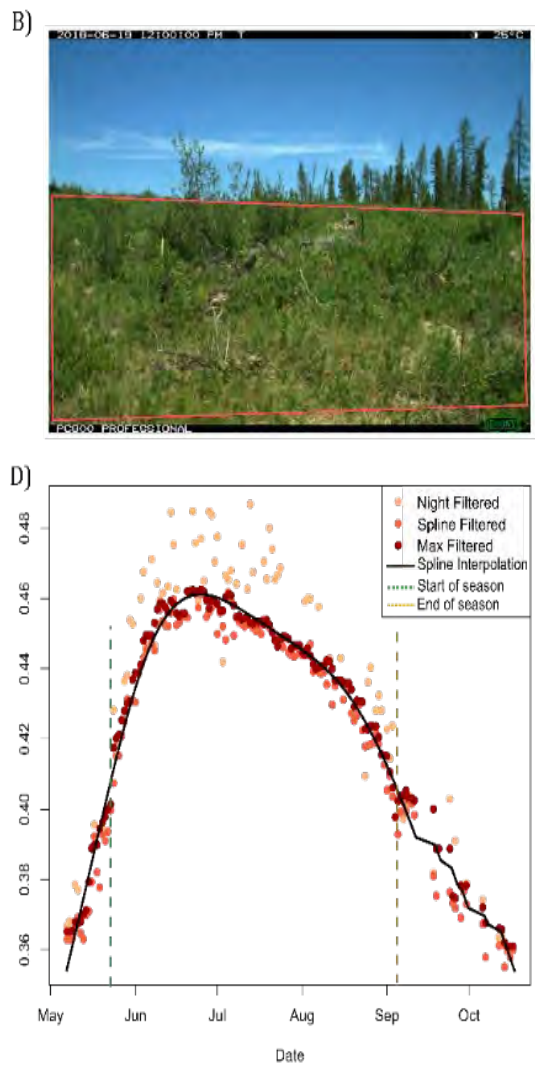

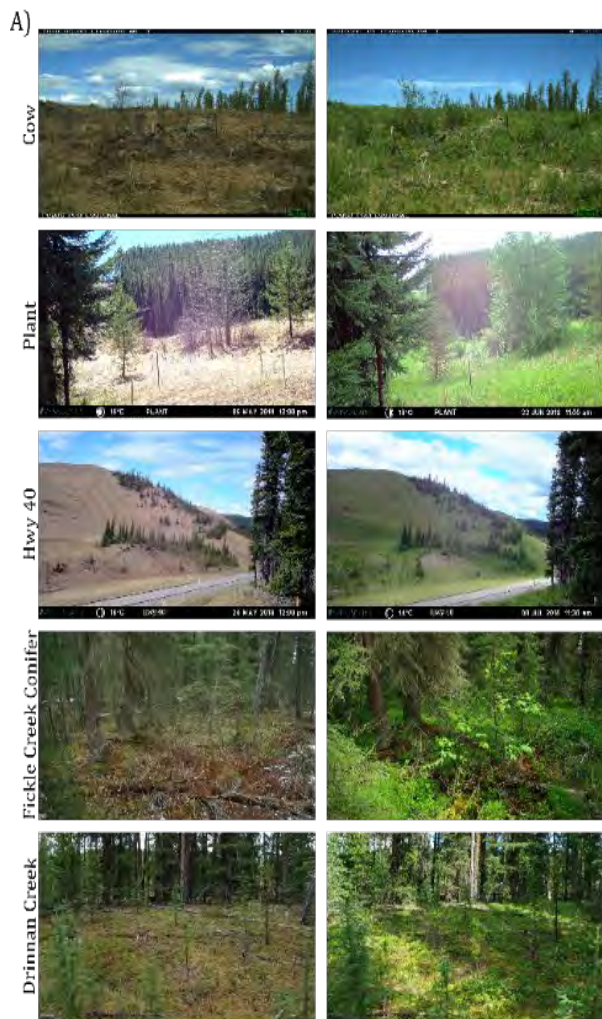

Are bears changing their behaviour with seasonal variations in understory food availability ?

Three Distinct Foraging Seasons

- Hypophagia (spring): Den emergence to mid June
- Early Hyperphagia (summer): Mid June to mid July
- Late Hyperphagia (fall): Late July to denning

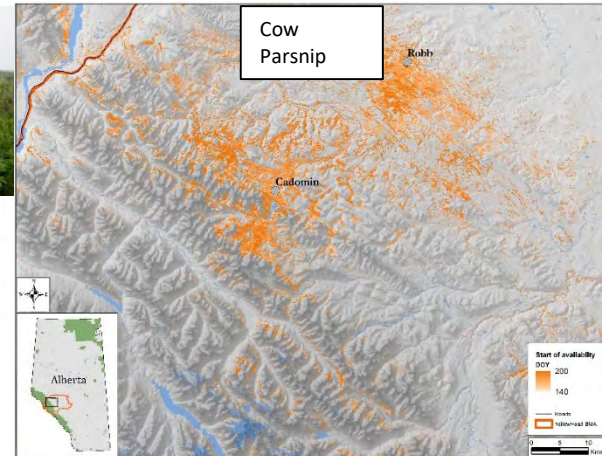

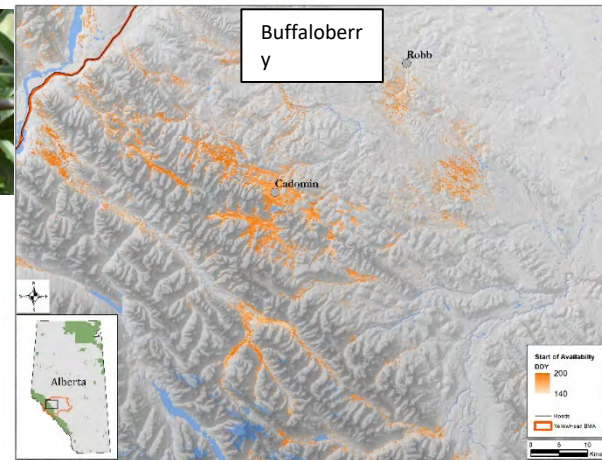

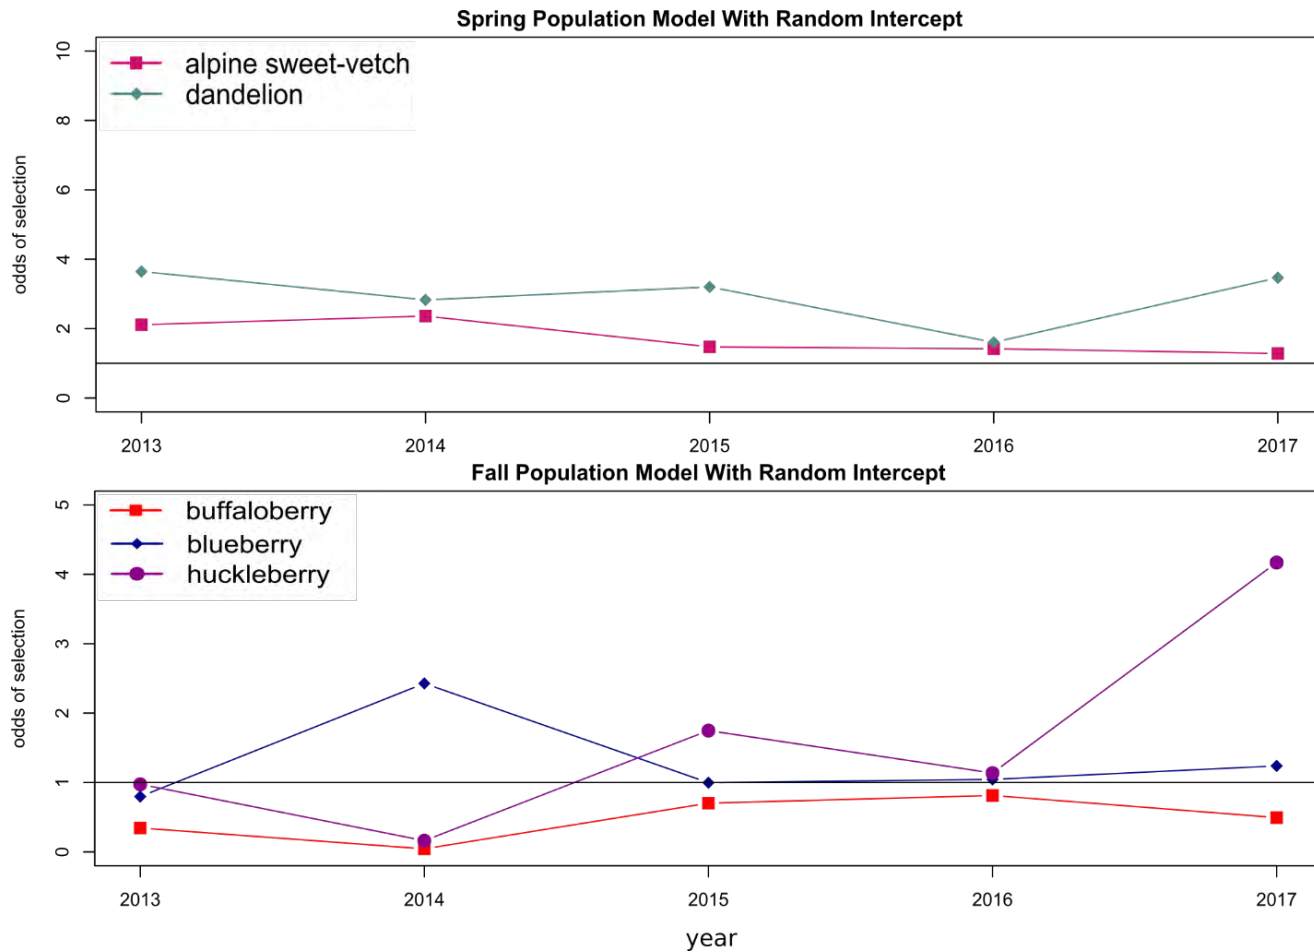

Availability layers

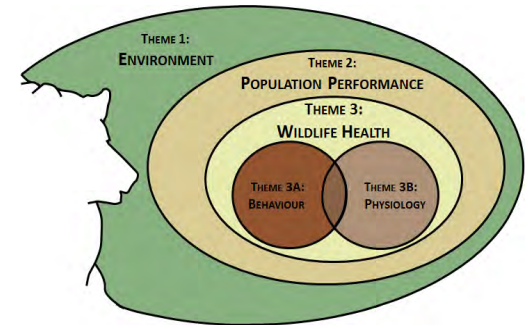

- Extracted availability windows using ground cameras and DRIVE data.
- Only include pixels with a probability of occurrence 80 percent or higher.
- Show day of year in which each species becomes available.

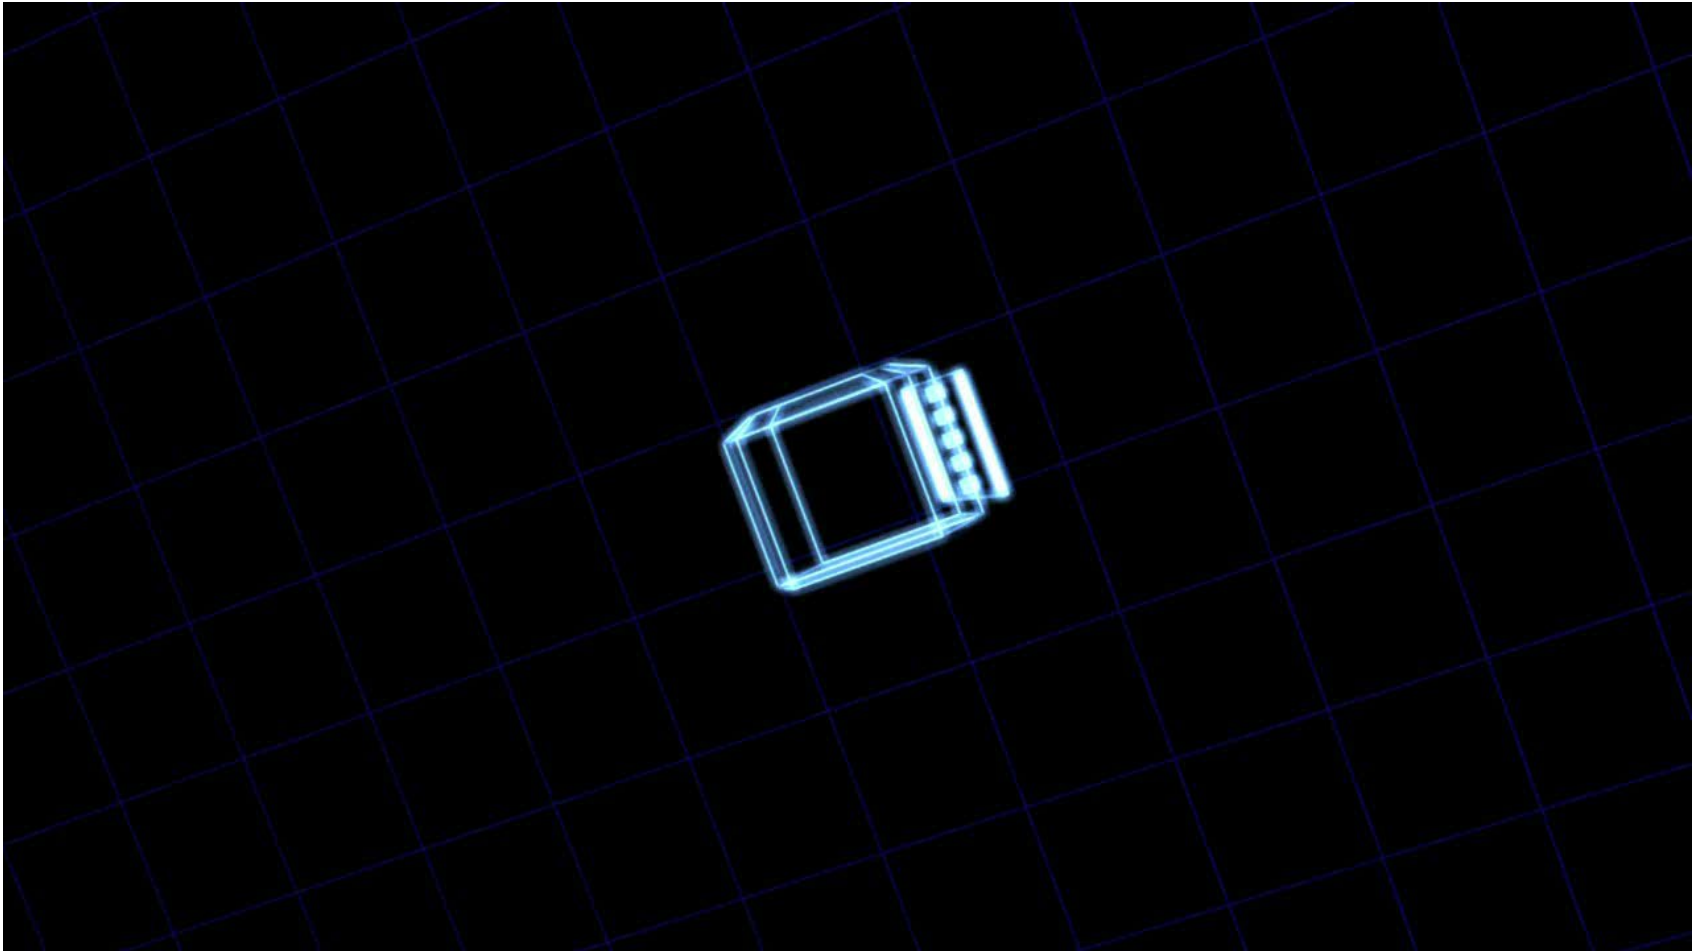

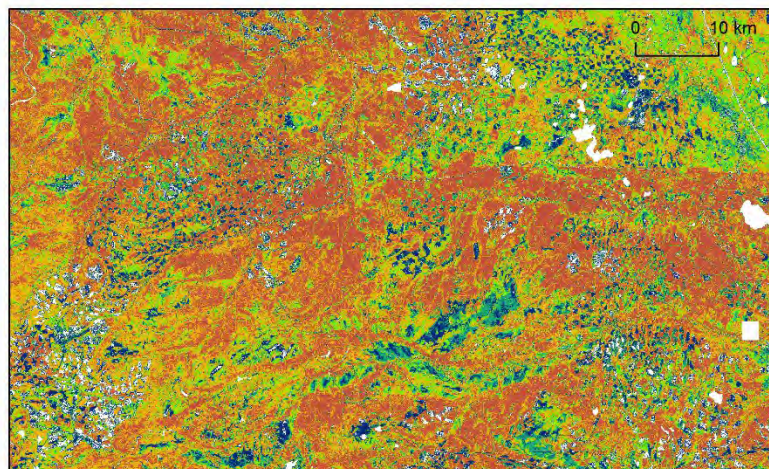

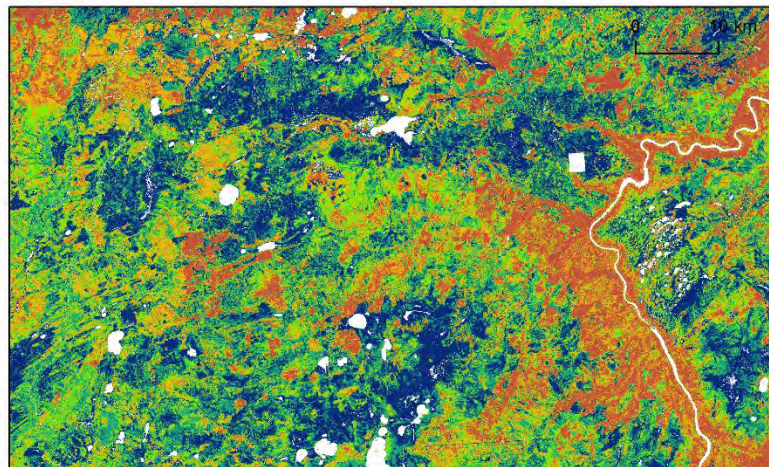

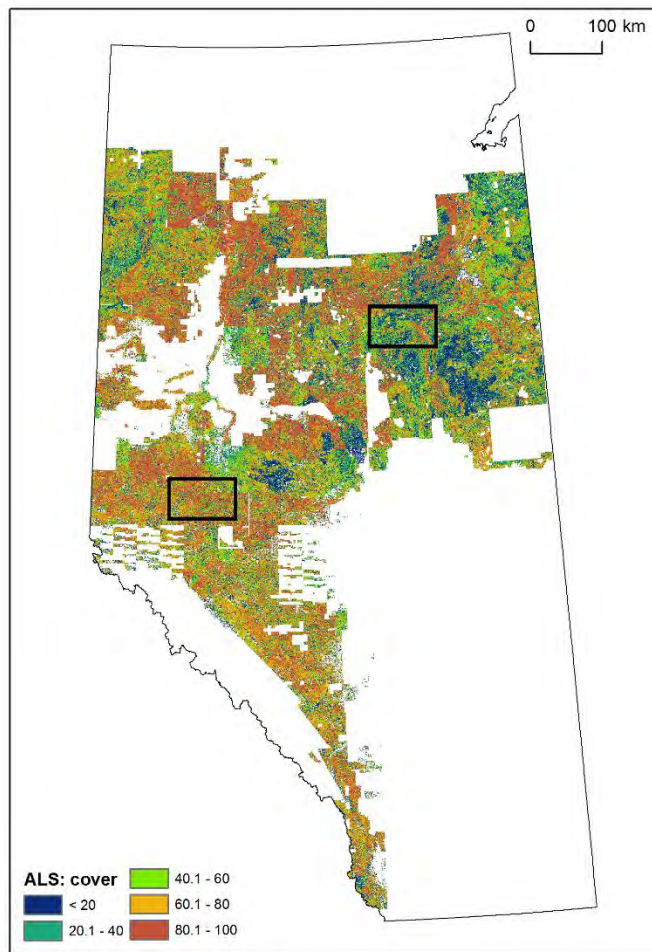

- Core model: Distance to roads + Terrain wetness index + distance to edge + land cover + elevation + insolation
- Food covariates
 - Was a bear within 100m of a individual food species at a time when it was “available”.
- Food models improve upon core model

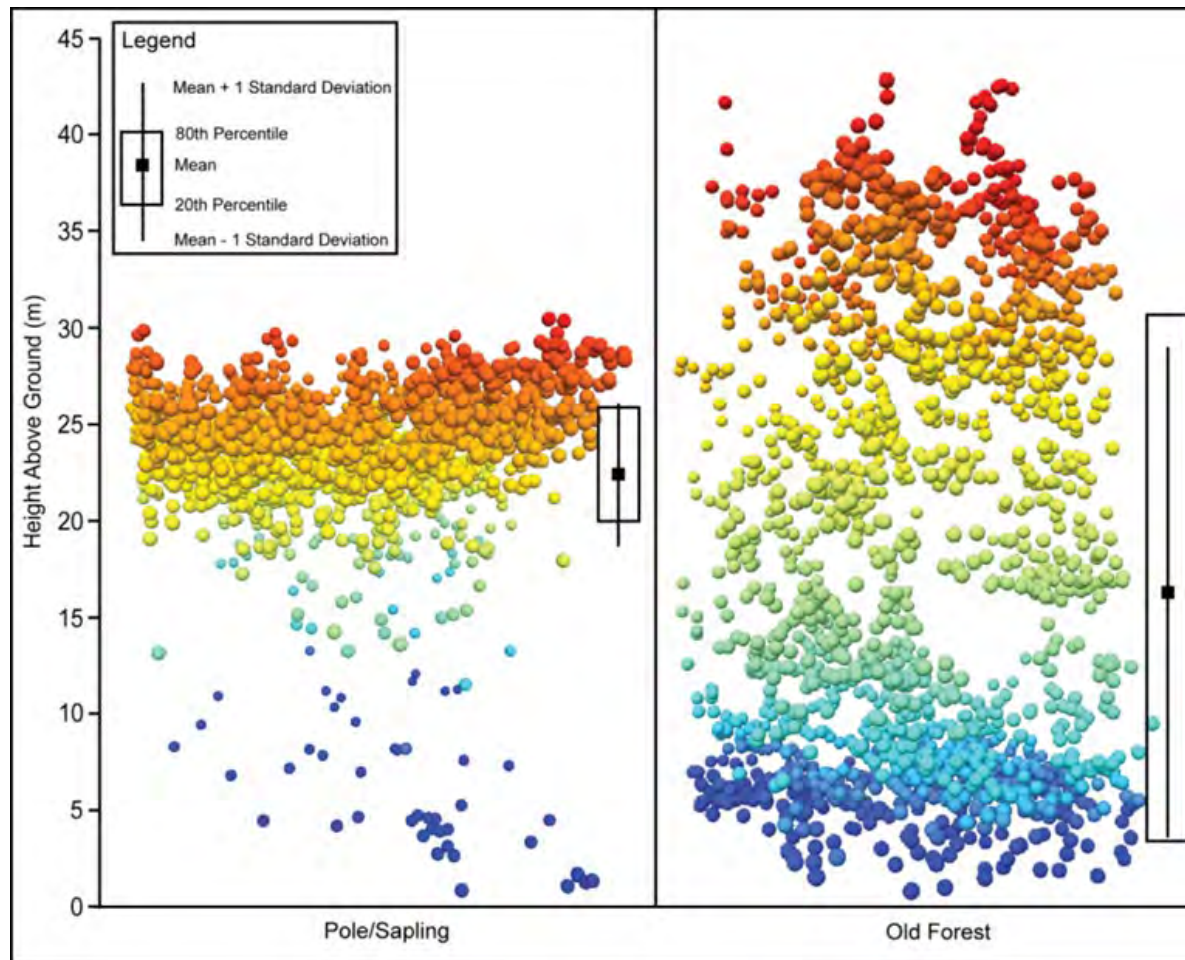

Does Changing Forest Structures Impact Bear Movement ?

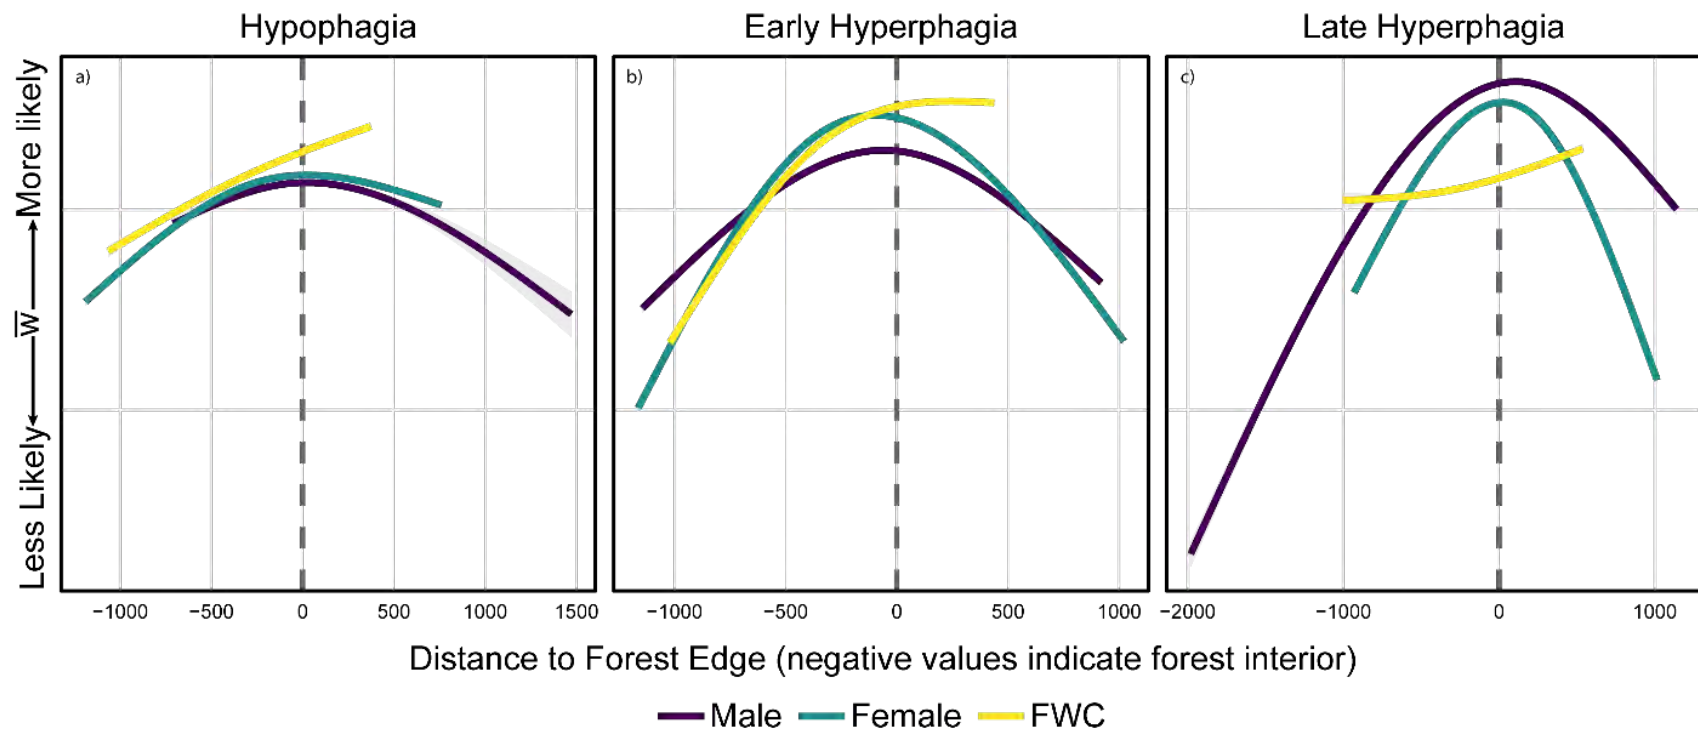

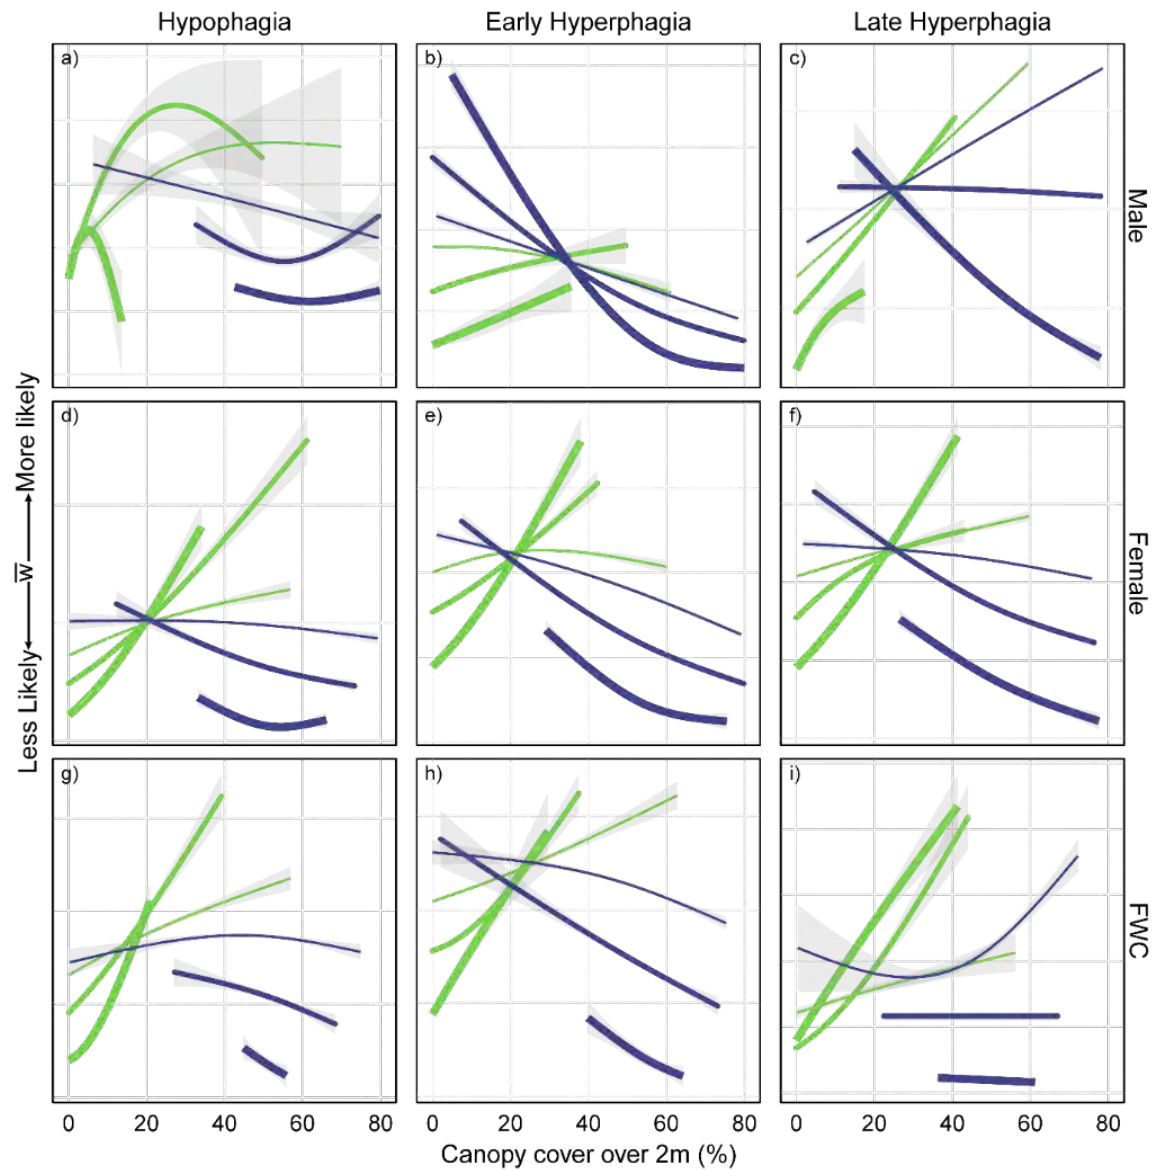

Do bears display preference for certain forest heights or canopy cover conditions?

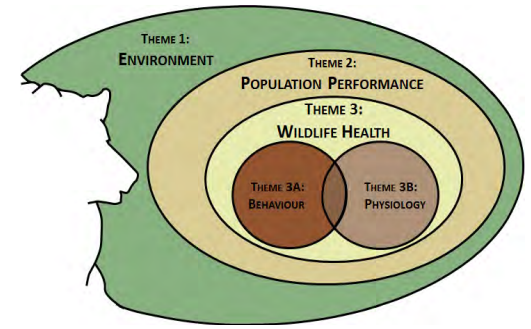

Outside Forest

Inside Forest

1km - 300m from edge
 300m - 100m from edge
 100m - 300m from edge
 <100m from edge

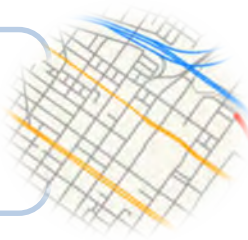

What road conditions, and use most impact bear movement and mortality ?

- A lot of studies have examined bear behaviour and roads
- We know:
 - Most mortalities human-caused near roads
 - 19/22 mortalities within 500 m of a road (Boulanger et al. 2014)
 - decreased reproductive success at high road densities (Roever et al. 2008)
 - But bears select for roads - potential attraction to roadside food
- Traffic dependent

Can we build a better model of how bears perceive roads in terms of what it sees and hears ?

Image-based classification

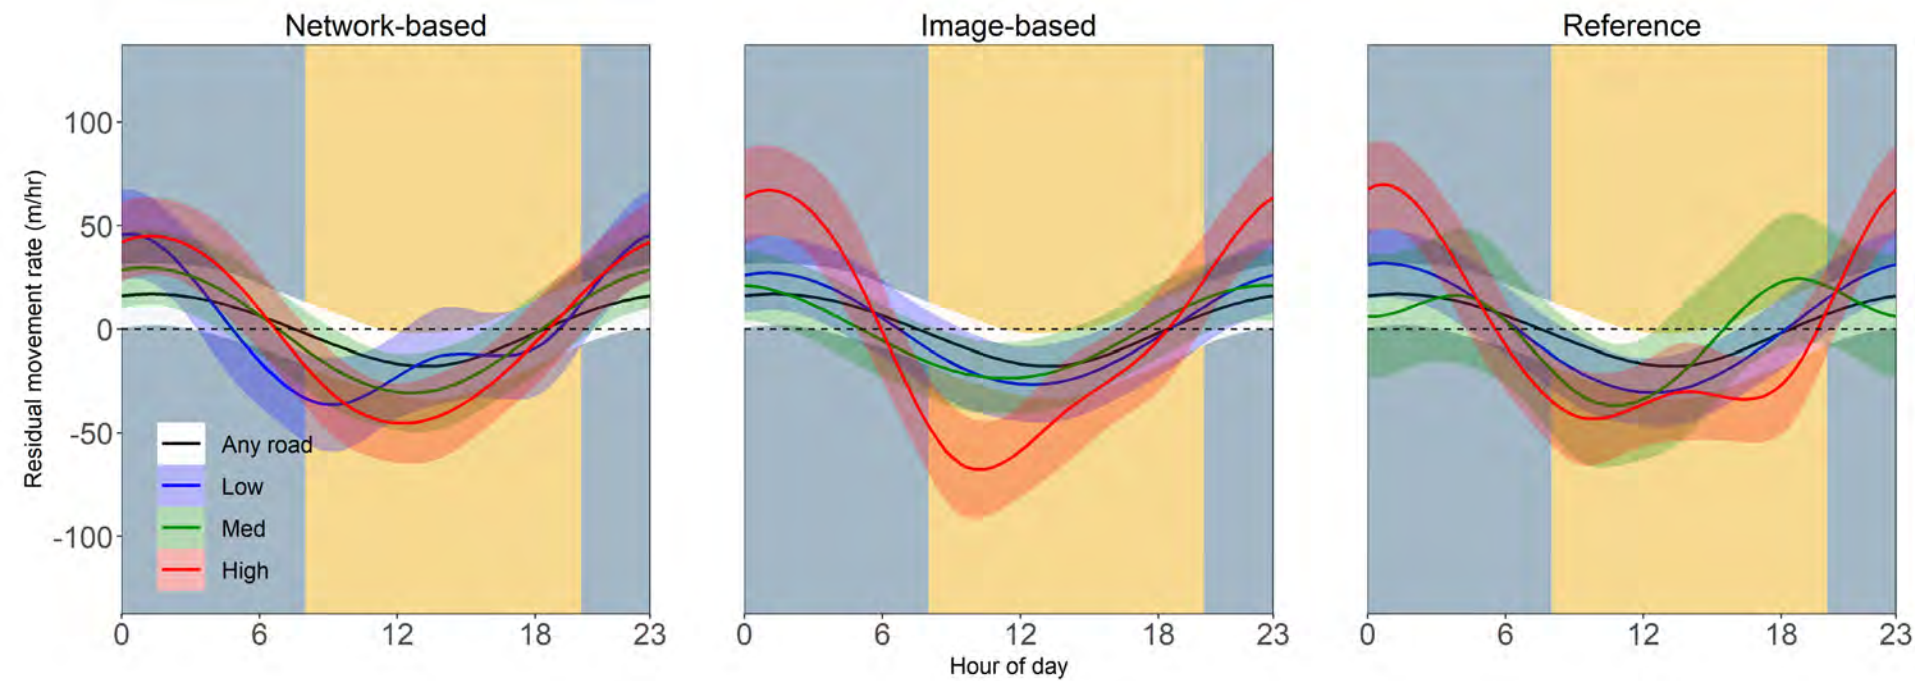

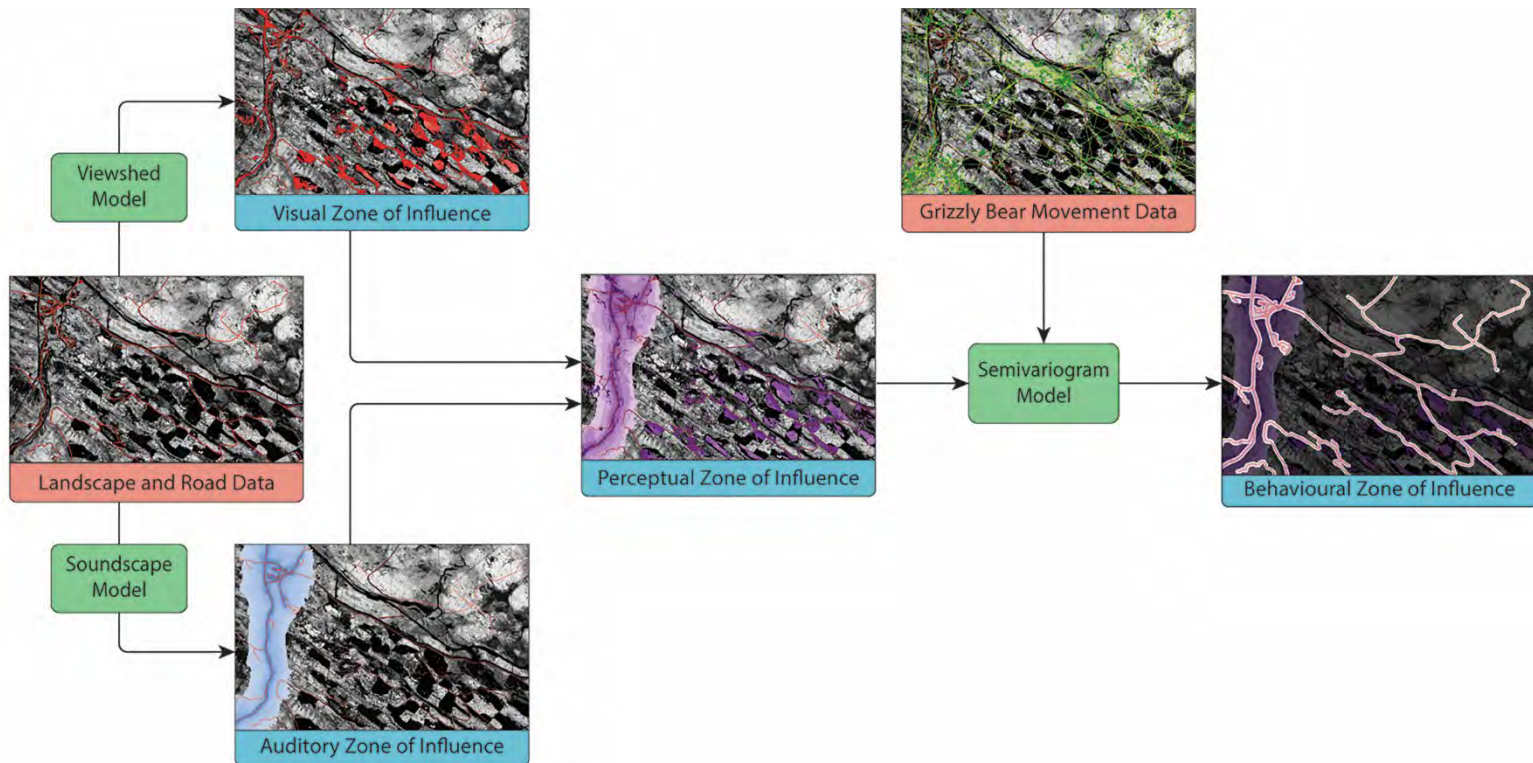

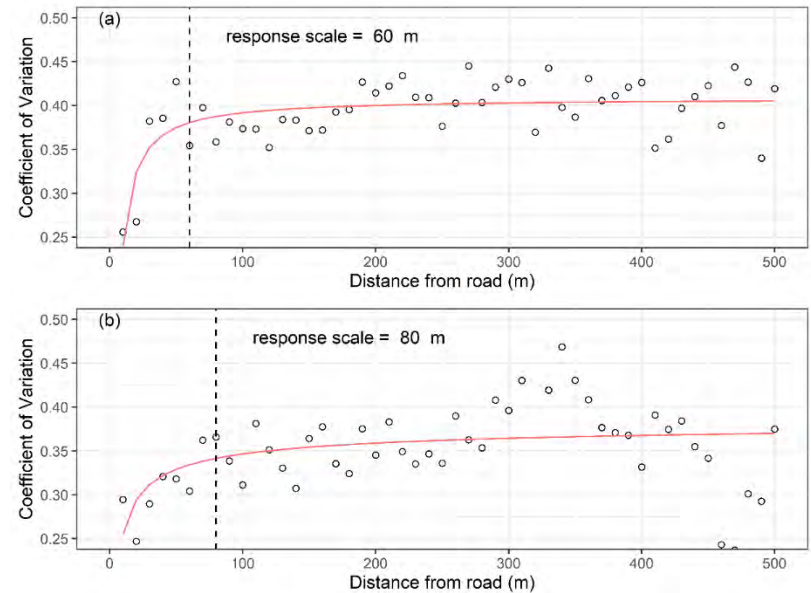

Figure: Diurnal deviation from expected movement rates by road class for the three classifications

Zones of Influence - Methods

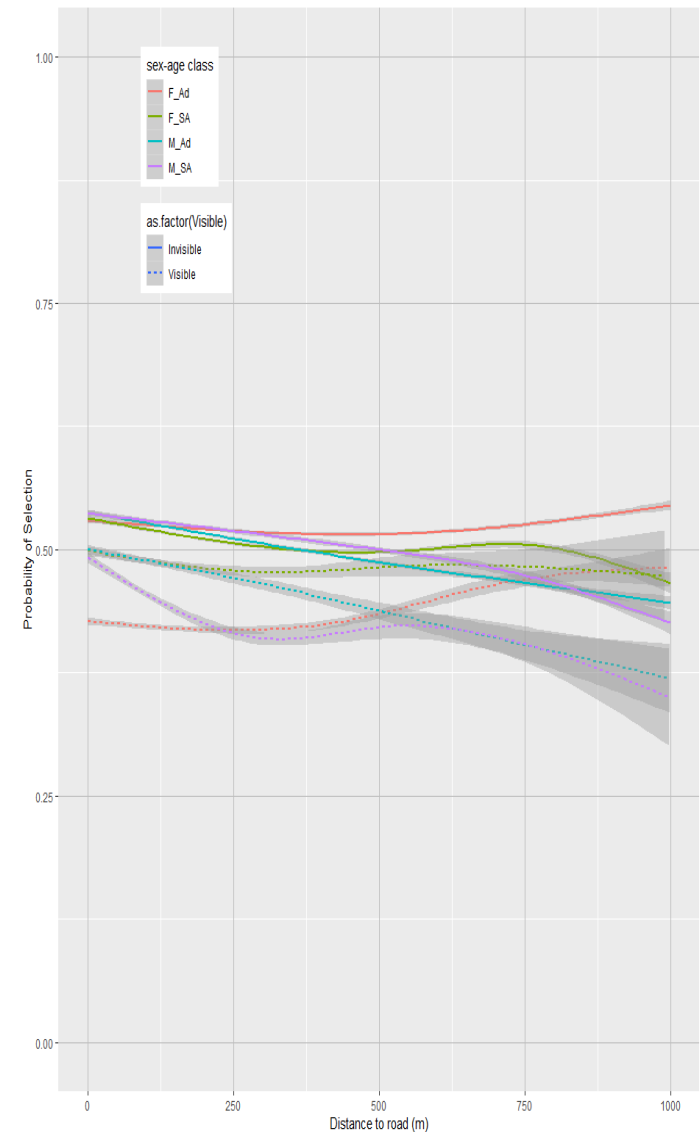

Zones of Influence - Results

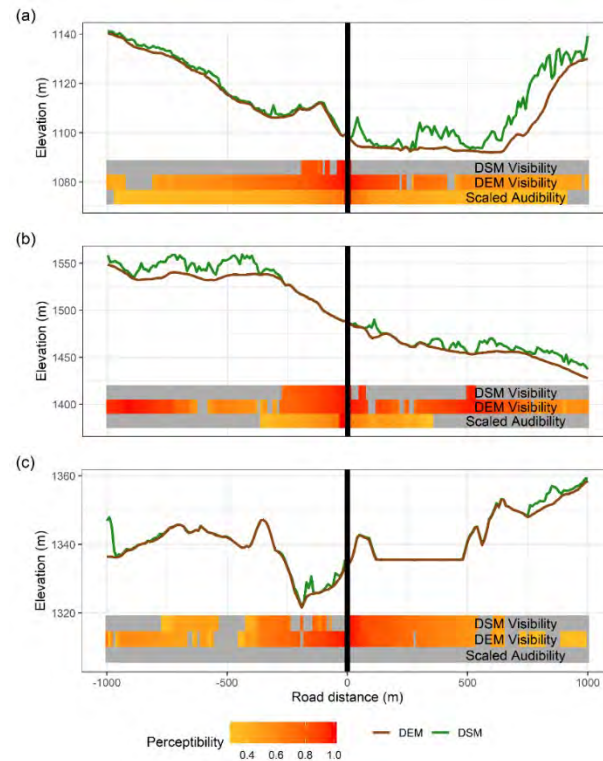

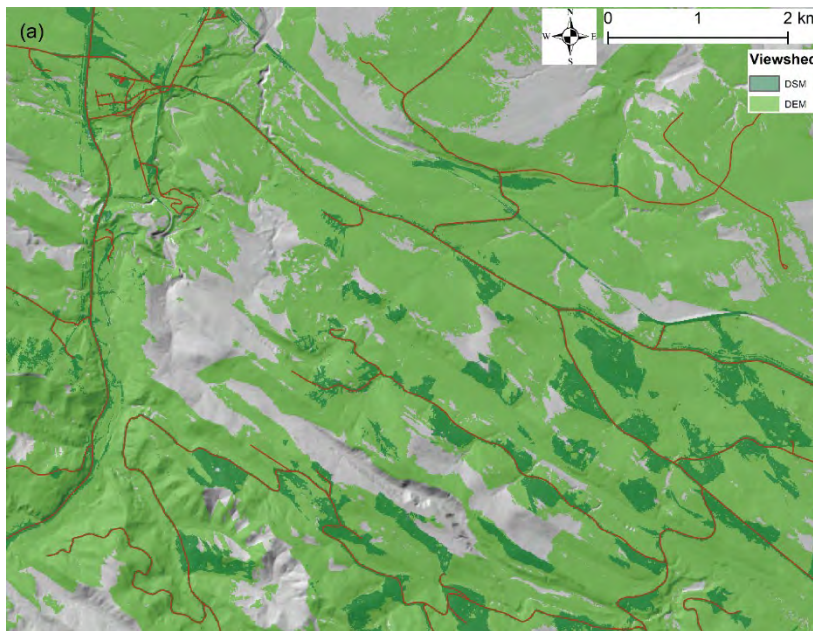

- Grizzly bears responded at further distances to roads when they could perceive the road than when the road was imperceptible

- Visibility performed better than sound or combined perception
- When compared to core and road models, visibility models are supported by 63/69 bears and 92.2% of the AIC weighting
- Grizzly bears tend to select for areas near the road, but prefer areas that are invisible to the road, indicating risk avoidance

Visibility and Forest Management

Geospatial Layers

- New approaches to map snow at fine spatial and temporal scales
- An ability to estimate the timing and phenology of understory vegetation across landscapes
- New methods to map roads in rural areas; and monitoring road development over time
- New approaches to map and perception of roads

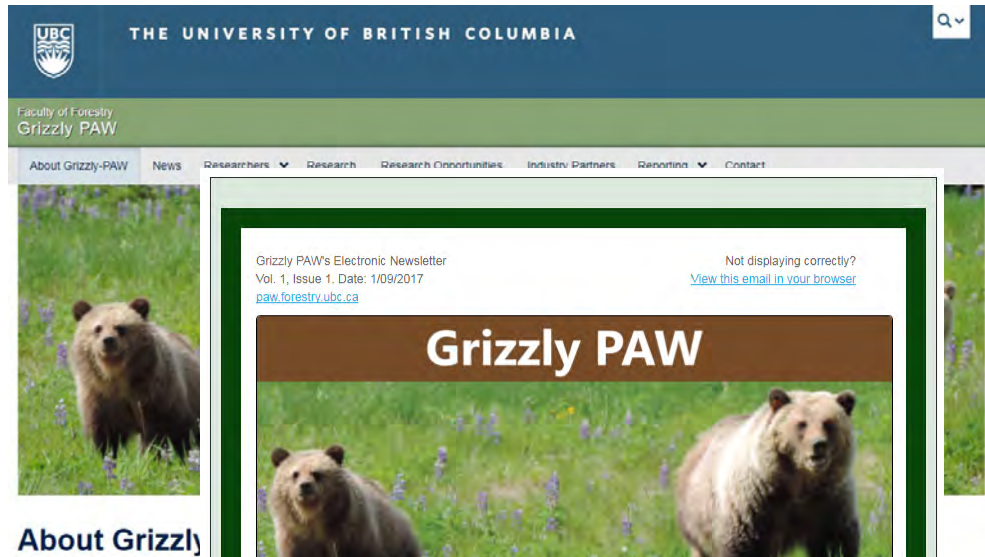

Key Takeaways

- Clear evidence that snow accumulation and melt times and onset of vegetation greening has changed over the past 18 years
- This research has found:
 - Bears are showing a clear response in their movement to snow cover
 - **More likely to use snow free areas and areas where snow melted sooner**
 - **More likely to use lower elevation locations, especially when snow free/earlier melt**
 - **More likely to use locations closer to roads, especially after snow melt**
- With respect to Den emergence:
 - Earlier melt end date = earlier activity date
 - More rapid melt rate = earlier activity date
 - Less consistent melt = earlier activity date

Key Takeaways

- Bears prefer low cover conditions inside forested stands, and outside stands they prefer high cover conditions. We are developing thresholds to allow us to get a better sense of what these limits might be.
- Roads influenced grizzly movement at greater distances when perceptible from roads
- Although grizzly bears selected for areas near roads, they preferred areas invisible to roads
- More deaths occurred in areas visible to the road than expected based on landscape availability
